The tests made at the Watertown Arsenal, referred to by Mr. Kenney, plainly demonstrated that the crushing strength of cubes, that is, the stresses per unit-area (not "the force to rupture cubes" as stated by Mr. Kenney) was a constant for any given material independent of the size of the cube. It was further proved by a series of tests made on similar prisms that the work varied as the volume, giving thus the *dementi* to Mr. Kenney's statement that "Stadler's theory (he means, of course, Kick's law) has nothing to do with prisms." It is, of course, for quite another reason that these tests are quoted. Two figures are picked out showing that less pressure was required to crush a cube than a flat prism of half the volume, while, "according to Mr. Stadler," just the opposite should have taken place. Even with a sketch under his nose, Mr. Kenney is not aware that a cube and a flat prism are not geometrically similar bodies and that the law could therefore not be applied. On the other hand, as the comparison of the crushing strength of dissimilar bodies showed that the breaking-load of the prism was greater, it follows from the application of Kick's law that a flat prism opposes a greater resistance to crushing than a cube of the same volume.

No scientist of standing has yet committed himself to a definite wording of the law expressing the so-called Rittinger's theory and each writer is therefore at liberty to make a version of his own. In Mr. Kenney's opinion "Rittinger's law in no way states that the work to rupture a cube is not proportional to the volume of the cube, neither does the law state that the work done is proportional to the diameter or square of the diameter of the cube ruptured. The law states first of all that the work done is proportional to the surface exposed in the operation," or putting it more briefly in the words of Mr. Gates: "Rittinger's theory is the law of the cracks" (cranks?). However, it must follow, that from the moment the work varies as the fractures exposed, as claimed above, it is bound by force of logic to vary also as the reciprocal of the diameter or inversely as the diameter, or as the square of the homologous dimensions; in fact, as any other series that varies at the same ratio. It would even vary as the mortality of children over certain ages if it should happen that the death-rate over that period should be the same.

For preventing misunderstandings it must always be kept in mind that any crushing law can be expressed in two different ways according to its referring to the work expended for reducing the whole of a body from its original size to a final size, or to the work required to cause the fracture of individual sizes. In the first case the work to be expended increases with the fineness of the final product in the proportion specified by the law and in the second case it decreases with the size of the body in quite a different proportion.

By following up his knife-theory Mr. Kenney arrives at the following startling conclusion: "As the cut becomes nearly complete, the potential energy of compression changes to work of fracture and the work of compression is lost as such." Before, we were told that by applying a knife no compression would take place and now he states that at the yield point (he means, of course, the limit of plastic deformation, or upset point) the work of compression changes to work of rupture, the former varying as the volume and the latter as the fractures. The curve of the total work expanded would in this case be a composite one, which it would be difficult to express in one formula. This difficulty, however, does not exist for resourceful men such as Mr. Kenney and Mr. Del Mar; they simply add the two equations and at the conclusion of the performance of some further

*M. & S. P., April 10, 1915.

†Trans. A. I. M. E., September, 1915.

algebraic parlor-tricks, Mr. Kenney triumphantly announces to the startled crowd: "Here is the agreement between the laws of Kick and Rittinger, showing how the work necessary to break cubes of the same material is at once proportional both to the volumes and the surface exposed by the break." The blunder of adding two laws is just as appalling as the error committed in this particular case is infinitesimally small, because the second portion of the curve expressing "the law of the cracks" is practically *nil*, considering that the distance through which the force has to move for severing the molecular bonds cannot be greater than the radius of molecular attraction. By observation of the happenings during the crushing of a specimen in a testing machine not the least indication of a critical stage immediately preceding the moment of actual rupture can be discovered. The strain-stress curve demonstrates that the force at the end of the operation of crushing approaches its maximum in a regular slowly-rising curve and at the same time the compression is vanishing and therefore also the work. In fact, the addition of a single grain of shot to the weight is sufficient to perform the act of final rupture, which consequently is nothing else than the ultimate end stage of the operation of compression.

Mr. Algernon Del Mar, lying sick in the same hospital as Mr. Kenney, displays an even more disquieting lack of technical training in his confused recent article.† He, too, differentiates between the work of compression and the work of fracture and, like his congenial friend, he handles the laws of work as if they were algebraic quantities. As a deterring example of technical twaddle the article merits re-printing in full, but the quotation of the conclusion will suffice to reveal the frame of mind of its author: "I have, I believe, shown that while Kick's law is true to the elastic limit, beyond Rittinger's law is approximately true for fracture, and the difference of the two amounts of work (!) is made up of several factors that vary with the size of the particle to be crushed."

With little respect for his theoretical achievements Mr. Del Mar is aware that this subject should "not be left to mathematical jugglery," but decided by experiments. Mr. Gates and Mr. Kenney are equally impressed by this necessity, but all three completely ignore that it is precisely by exhaustive experimental work carried out in well equipped testing laboratories by qualified experts that all these problems were solved and definitely settled—half a century ago.

Saving Fine Gold

The Editor:

Sir—I have read with much interest the various articles which have appeared from time to time on the subject of concentrating placer material. The purpose is to save the gold and platinum that exist in a very fine state of division and in the form of thin plates. Metal in these forms occurs in the black sands and cannot be separated from them by means of the usual sluice and riffle. The best that can be done is to save the black sand and then, after concentrating the metal in a part of the black sand, separate the portion of the black sand that has little or no value, and ship the rich sand to a refinery or smelter.

Such concentrating plants appear to have been more or less successful. As near as I can determine, where they have failed it has been due to known causes, as follows: (1) High charges for refining; (2) high cost of freight; (3) inefficient concentration plant; (4) high ratio of concentration, by which much of the metal went over in the tailing and too much expense for concentration was incurred.

After about six years' study of this problem, accompanied by practical test at various mines, I have arrived at the following solution: The sand is worked in two stages on account of the uneven feed from the sluices; it is fed from an undercurrent onto a roughing table and from this passes into a bin or tank where it is dewatered to some extent. A regulated feed of sand and water is then passed to a finishing table. From this a $20 concentrate is passed over an amalgamated silver plate which has riffles resting on its surface. The ends of these riffles are fastened to narrow strips of wood about three feet long, forming a sort of rack that can be moved along on the plate so as to utilize every part of the surface. These racks can be taken off with the plate with one movement when it is desired to clean-up.

The riffles furnish a succession of drops the importance of which in saving fine gold is commented upon by R. H. Richards in 'Ore Dressing,' and other authorities. Since the plate below each riffle cannot become blanketed, each particle has an opportunity to strike the mercury. A riffle-block $\frac{3}{8}$ inch high, $\frac{1}{4}$ in. wide, and 4 in. from the next one on each side is preferred.

Where there is platinum in the sand, or where the gold is difficult to amalgamate on account of oxide, greasy, or silicious coatings, I use an electrified riffle-block insulated from the plate by means of a strip of wood or other nonconductor. These riffle-blocks are held in similar racks. Salt solution is used to feed the sand over the riffles, and sodium is deposited from this into the mercury by electrolysis. The hydrogen formed at the plate removes oxide coatings. Caustic soda produced from the salt solution by electrolysis removes silica and grease. The 'quick' is always bright and never flours; a 100% extraction is not unusual where the metals are not wholly encased. The electrical efficiency is high on account of the nearness of the anodes to the plate. The cost of extraction when spread over the total yardage is from a fraction of a cent to several cents per yard, exclusive of concentration. The cost of concentration is much reduced because of the low ratio. All freight and smelter charges are done away with and an almost equally high extraction secured with no loss in fume.

The apparatus is inexpensive and simple to operate.

†M. & S. P., May 1, 1915.

It can be installed by any electro-metallurgist after he has familiarized himself with its details. Since the ratio of concentration would hardly ever be less than 40:1, only a limited plate-area is necessary, and the capacity of the plant is dependent only on the amount of material that can be concentrated to the value of $20 per ton in 24 hours. The plate has generally a grade of about three inches per foot, thus reducing the sand-bank formed in front of the riffle-block or anode to the minimum, and reducing the amount of solution necessary to wash the black sand over the plate.

The gold and platinum in the black sand, after passing over the electrified riffle-block (anode), drop nearly straight down to the plate while the lighter black sand strikes the plate somewhat farther down. If the metals are not immediately amalgamated they drag slowly down to the sand bank in front of the next riffle-block where they work underneath the sand through the mechanical action of the solution. At the same time they are thus brought into and held in the zone of electrical action and are soon amalgamated. Most of the metal is caught in the first foot of the plate. Sodium is deposited continuously and has little chance to oxidize in the salt solution. When it is desired to clean-up, the riffle-racks are removed, the amalgam scraped, squeezed, and placed in water for a few hours or until the sodium is oxidized, when platinum will no longer be held. A little fresh mercury is added; this picks up the gold amalgam and leaves the platinum. The usual methods of treatment are then followed.

Valuation of Metal Mines

The Editor:

Sir—The results of the valuation of Michigan's mines in 1911 by Mr. J. R. Finlay have come in for criticism as well as praise. The criticism has come mostly from Lake Superior; it has been based partly on the arguments that the numerical factors assumed by Mr. Finlay, such as 5% as the dividend interest and 4% as the rate of amortization, are unfair to the mining companies. Another objection is that, while the system of appraisal is perhaps technically admirable, in practice it discourages exploration and blocking-out of ore in advance, because as soon as additional reserves are proved, the taxes are increased just that much. Mr. E. E. White of Ishpeming prepared a careful criticism of Mr. Finlay's results, to which (as I remember) Mr. Finlay replied rather weakly.

Another vigorous dissenter to increase of iron-mine assessments by the Finlay system has been Mr. Thomas Walters of Ishpeming, for many years Lake Superior agent for Jones & Laughlin. Mr. Walters claimed, with some apparent justice, that the Lake Angeline mine was taxed out of all proportion to its actual value, merely because Mr. Finlay had assumed or guessed that the old mine, which was nearly exhausted, would continue to produce as it had in the past. The Lake Angeline mine was a remarkable money-maker in its day, both on account of richness of the ore and for the reason that under the skillful management of Mr. Walters and his staff, a praiseworthy efficiency was maintained over a long period of years. Because this assessment was based largely on the mine's past record, it was contended in Ishpeming that the State of Michigan was taxing the brains and initiative of the mine-staff. Of course, in refutation of this, it can be pointed out that a man who is taxed on his income or improved property is being penalized likewise for having brains and ability, so that one case is no more unfair than the other. I was in Ishpeming last month, and on the day I arrived, the Lake Angeline mine (which is close to the trim city of Ishpeming and includes scores of dwellings and a large acreage of land) was sold at auction for the ridiculously low sum of $27,000. It seemed as though Mr. Walter's contention, that the famous property had been over-assessed, was proved.

As indicative of the difference between a Michigan mine's assessment by the State Tax Commission and its value for the purpose of re-sale, there is pertinent the case of the Republic iron mine sold two years ago for $600,000 by the Cambria Steel interests to the Cleveland-Cliffs Iron Co. This mine was assessed that same year by the State at $1,040,000, and the next year for $1,110,-299, which is nearly twice the sale-price. In addition to paying only $600,000 for the mine, the deal with the Cleveland-Cliffs Iron Co. included the transfer of 4000 acres of land, and a favorable contract from the Cambria Steel Co. for supplying iron-ore over a long period.

A Curious Nugget

The Editor:

Sir—The enclosed photograph is of a gold nugget shown to me by Mr. Fred. U. Best, in the Canadian Pavilion, last spring. I was so interested that I asked him to let me have a photograph of it. My object in sending it to you is that it may throw some light on the

THE NUGGET.

formation of placer gold. The gold was clean, bright, and free from rock, and, would seem to me, probably to have been formed in place.

The nugget was found by Mr. Best on Bonanza creek, Chisana, Alaska.

F. H. Mason.

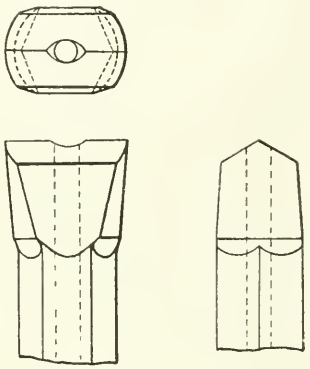
Rock-Drill Bits

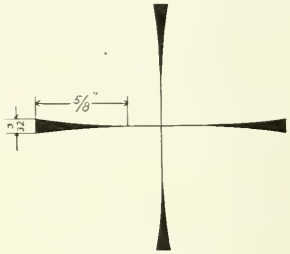
By P. B. McDONALD

Much interest nowadays is manifested in drill-bits. For hard rock, where loss of gauge is a determining factor, the new Carr bit of the Ingersoll-Rand Co. is giving excellent results. The Calumet & Hecla Co. is using this bit extensively with the Leyner-Ingersoll drill, a mounted hammer-machine. Tests have been made by C. R. Forbes and L. M. Cummings in Missouri, to investigate the relative efficiency of piston-drill bits, such as the Z-bit of the southeastern Missouri type, the Joplin 'bull' bit, and the 'flat' cross-bit. By the flat bit is meant a regular cross-bit with edges slightly flattened in proportion to the distance from the centre; a low-centre



THE CARR BIT.

cross-bit is similar to the flat bit, because it soon wears to practically the same shape. The conclusions reached in these tests were: that for piston-drills in granite, long-winged flat bits are very satisfactory; the Z-bit appears to drill especially fast at the start, but loses gauge rapidly; the Simmons bit (a Western bit with one cutting edge advanced, the other being flat and serving as a reaming tool) gave results similar to the Z-bit; an increase of air-pressure from 70 to 85 lb. (about 17%) using a C-110 Ingersoll-Rand butterfly-valve piston-drill in granite with regular bits effected an increase in drilling speed of from 30 to 50%. In one test, using a flat bit, the remarkable distance of 22 ft. was drilled in granite without re-sharpening and at an average speed of nearly 4 inches per minute; this bit wore from $1\frac{3}{4}$-in. gauge to the size of the inch octagon-steel. The generally wider use of bits that will hold their gauge satisfactorily in hard rock, such as the Carr and flat bits, is tending to the practice of drilling longer holes for stoping. In some districts this system of deep drill-holes is reducing costs to a surprising extent. By blasting long holes (say of 12 or 14 ft.) on a large scale, great masses of ore can be broken that, if necessary, can be block-holed by jack-hammers. This system is more efficient than the former method of blasting short holes (say, of 6 ft.). Of course, where the ground is dangerous or irregular, deep holes may be impracticable, but in homogeneous rock the large-scale blasting is apt to be much more efficient. With Carr bits, the reduction in gauge of bits on successive lengths of drill-steel can be as small as $\frac{1}{16}$ inch, which is a factor of tremendous importance in hard rock. There is a tendency to use compressed-air at a higher pressure than formerly for rock-drills, although at some mines this change has come indirectly through utilizing the same



A FLAT CROSS-BIT.

air-plant for smaller modern drills that had been used previously for drills requiring more air. In regard to the proper hardness of drill-steel as indicated by the amount of carbon in the steel, authorities claim that the harder the rock the softer must be the steel, for the reason that the bit will not stand the impact if too-hard steel is used to drill hard ground; this sounds paradoxical at first, but logical enough when carefully considered. The practice of punching a hole in the side of hollow drill-steel for mounted hammer-drills of the Leyner type, an inch or two from the end of the bit, is a common aid to better drilling in soft rock where the bit tends to clog with rock-chippings or mud.

Fuse

The Coast Manufacturing & Supply Co., which manufactures much of the fuse used at Butte, gives the following suggestions as to the proper handling of fuse in blasting.

1. Cut fuse squarely, not slantingly, at the end that goes into the cap. A pointed end is liable to get turned over in warm weather when the fuse is pushed into the cap, resulting in a misfire. Or, in cold weather it is not particularly safe to jab a sharp-pointed hard piece of fuse into a cap.

2. While axle-grease or crude-oil may have some water-proofing qualities if applied to the outside of a fuse, when capped, to make a so-called water-proof joint, grease and oil are solvents of the varnish on the fuse and consequently may destroy the powder-train with as great rapidity as the water which the miner is trying to exclude.

3. Don't use fuse that has been hammered or injured by falling rock, as such injury increases the burning rate; there have been instances when a fuse hammered in this manner burned almost instantaneously.

4. Don't hesitate to cut an inch of fuse from the end; as this will prevent the damp ends from getting in the caps.

Air-Froth Flotation—II

[In our issue of October 16 we gave an excerpt from the speech made by Mr. W. A. Scott, counsel for defendant in the case of Minerals Separation, Limited, *v.* Miami Copper Company. We follow this now with lengthy quotations from the speeches of Messrs. Henry D. Williams and W. Houston Kenyon, of counsel for the complainant. In the first excerpt Mr. Williams discusses the article by the three students at the University of California, as published in the college magazine, *The California Journal of Technology*. The major portion of that article appeared in our issue of July 31, 1915, to which the reader is referred in order to follow the lawyer's remarks. In the second and third excerpts Mr. Kenyon discusses some of the physics of the flotation process. Of course, the reader must remember that this exposition of the subject, like that of Mr. Scott, is not to be taken as a scientific thesis; it is essentially an *ex parte* explanation, but even as such it is extremely interesting to metallurgists. The first patent in suit, to which reference is made, is No. 835,120.—EDITOR.]

MR. WILLIAMS: *The California Journal of Technology* is evidence of the interest that the metallurgical world took in the Elmore process. The title is 'Experiments on the Elmore Process of Oil Concentration.' The conclusion is:

"The work above outlined suggests many lines of further investigation, and as these come to be worked out, the process will become more valuable and of more general application."

What process? The Elmore process.

In 1903, the Elmore process was a hope of the metallurgical world.

Incidentally, the students discovered something else, and, for the first time, gave to the world the foam effect. Full disclosure as to a mode of operation which would produce an oil foam, they, for the first time, in the history of metallurgy, gave to the world.

That was an incident of their careful investigation, but the article itself is on the Elmore process, and it says that the Elmore process was then a hope of the metallurgical world.

THE COURT: Mr. Williams, if there was a disclosure of the process, although a misnomer, what would be the effect of that disclosure?

MR. WILLIAMS: The name, obviously, has nothing to do with it.

THE COURT: No.

MR. WILLIAMS: I was particularly directing my attention to the fact that Mr. Sheridan took those last three lines as something which was directed solely and wholly to that small part of this article which deals with the foam effect.

THE COURT: Oh, I understand.

MR. WILLIAMS: And I was merely pointing to the fact that those lines must have referred to this Elmore process as a hope of the metallurgical world.

The foam effect here disclosed, which is recommended as employing 8.9% of oil—it being clearly shown that nothing else is worth anything—8.9% of oil and salt solution, an ore containing light flaky minerals, such as molybdenite; and another one of the same kind is graphite, and I do not know any others—certainly not copper, certainly not zinc. Galena and blende are not flaky. Galena is almost cubical in its fracture. They call attention to the study of the fracture of minerals. They have worked out this foam effect, which they give to the world, with the recommendation that 8.9% of oil be used, as something which may possibly be useful with light, flaky minerals, and that became a part of the constructive knowledge of the world in November 1903.

It is remarkable that it was buried and lost, and that it took three years of litigation to unearth it. That is quite remarkable, especially that it should have been buried and lost in the University of California, which is in the heart or the centre of the important mining interests on the Pacific Coast, and in the Great West.

But that is all there is there, and the most significant thing about it is that it tells the investigator: We have tried 2.1%, and the result is hopeless. We have tried 5.3%, and the result is almost as bad. But we have tried 8.9%, and there is some hope in that. Now, proceed; investigate.

But very evidently, nobody proceeded and investigated. There is not any practical art, unless it be Elmore. There was not any mill that made any use of any of these patents that have been referred to. Haynes lightly touched upon; Everson, the foundation of the defendant's case—why these very students in this article tell the exact truth about Everson. I am sorry they did not write more, because they would have been impartial, and they would have possibly given us a fair, unbiased interpretation of the patent.

"In 1886 Carrie J. Everson of Chicago* contributed the idea that the concentration was aided by the presence of an acid solution, and patented the same."

That is just exactly what Carrie Everson did contribute. It is an exact statement, and that is preceded by reference to another patent, which the defendant has not seen fit to refer to, although it has figured in some of the other litigation—the patent of Tunbridge, erroneously here spelled as 'Turnbridge.' That is set forth here as the first patent for utilizing oil, and its date is given as 1878. But it is of slight relevancy, and the defendant has not relied upon it, and it is, as your Honor will note, later than Haynes.

*In her first Patent, No. 349,157, she is described as "of Chicago, Illinois" but in No. 471,174 she is said to be "of Denver, Colorado."—EDITOR.

As a matter of fact, the reference to this patent would indicate a study of the Everson patent, because the Everson patent disclaims the Tunbridge patent. It does so with quite some labor. It is the thing that Carrie Everson had to distinguish from; that I think accounts for the reference to that patent.

These students probably investigated the patent situation, and so they referred to the Tunbridge patent and the Everson patent, and they tell the exact truth of the contribution of Carrie J. Everson to the art of the idea that the concentration was aided by the presence of an acid solution.

Then these young men say, and they say truthfully:

"But the absence of a successful method of separating the mineral from the oil prevented the practical application of these prior patents."

Well, they do not tell the whole truth about that, but that is undoubtedly one of the reasons, and the important thing is that these prior patents, Tunbridge and Everson, were not practically applied. That they were not capable of practicable application would be the reasonable presumption, but that is the fact. And then these students go into the subject of the removal of the oil. Of course, with 17.1% of oil, which is 342 pounds of oil to the ton of ore, and if out of the ton of ore you got 700 lb. of concentrate, that would be a fair average. With these 342 lb. of oil, you see the oil would be about 50% of the concentrate. You would have a great mass of oil with the concentrate, and unless you could successfully get rid of that oil, it would be troublesome; and, again, the cost of that oil was such that it must be possible to recover and use it over again. It has acted merely in a physical manner. It has not changed its constitution at all. So, if you could bring it out, separate it, and send it through again, there was some hope; it was Elmore who did that.

The students say that burning of the oil was tried, which left a difficult residue to treat, and the large consumption of the oil made the method too expensive. That is undoubtedly true.

"It was not until July 1900 that this difficulty was overcome by means of a special machine, similar in most respects to that which is used in sugar factories and in milk and cream separation. This contribution by Mr. Elmore then made the process feasible."

Now, we will note here that they mean the process of oil concentration. These young men were looking at it solely from the viewpoint of something which utilized oil in the concentration of ores—they were not concerned particularly with methods, but they were looking at it always from that viewpoint; that is why they refer to Tunbridge, and why they refer to Everson, but there is not a thought or suggestion running through here that the Everson patent, which they say has proved of no practical value, makes any suggestion of flotation. Everson merely contributed the use of acid.

Mr. Williams: Prior to the invention of the first patent in suit, and looking only to what men did, we find that wet-concentration processes were the solution of the ore-concentration problem. They were the processes that have been described here, and that I need not describe again; processes that depend upon gravity and shaking and motion of finely ground ore suspended in moving water, the separation depending upon the difference in sinking-power of the metal and the gangue; wet-concentration processes that are in use to a tremendous extent still, but that are being superseded in the last two or three years to an astonishing degree by the processes of the patents in suit.

Now, in these wet-concentration processes advantage was taken of the fact that the metal had a higher specific gravity in the average than the gangue, and the laws of nature were followed. The heavier thing was allowed to settle, and circumstances and conditions were so controlled that it would have a chance to settle away while the gangue would be left suspended. The gangue would be floated in mid-bulk of the liquid, and up and down and all around, and finally floated off over a dam.

But all wet-concentration processes—and the machinery for carrying them out has exercised the ingenuity of inventors for thirty years—all wet-concentration processes were useless on slime, and the fact that the concentration was by such processes raised a hard and fast limitation to the extent that you could grind your ore. The grinding must be coarse. The grinding must be so done as to produce the minimum of metal-dust; and so grinding machines were invented to that end, to prevent the production of the fine dust-like particles of metal in the general grinding of the ore. All wet-concentration processes are useless on slimes. They will not settle. They will not obey the laws of gravity. They will stay up with the gangue. They will float off with the gangue. They will run to waste. And hence we have these tailings in Australia and here, of millions of tons, where the slimed metal, the finest of the metal, has all run off, because it could not be recovered. With such concentration processes the best that could be done was from 60 to 70% recovery. Prof. Fulton gave 70% as the outside limit—60 or 70% of the sulphide metal in the original ore. And yet men persisted in using that process.

Elmore, about the opening of this century, about 1900—his patents were a year or two earlier—came in with his process to reverse the laws of nature. Instead of finding the heavier thing at the bottom, Elmore said: "I will carry it to the top."

Again a process useless on slime. Again a process requiring coarse grinding as before. The concentrate at the top now instead of at the bottom. The theory of operation was an oil lake. I like that word 'lake.' It is used by the *California Journal* students—an oil lake. Air entrainment was fatal. Ingenuity was exercised to so mix the oil lake and the ore as not to entrap air. Oil-emulsion was fatal. The amount of oil we know was 100 to 300% on the ore. And yet men did that thing. Men paid that price, and the loss on every 100 lb. of oil was 9 or 10 lb. at each cycle. The other 90 lb. had to be taken out, and preserved, and used over again.

And Cattermole. The very men who afterward made the invention of the first patent in suit, spent two years and a half developing that Cattermole process, a really

beautiful idea, the first process addressed to the slime problem. Said Cattermole to himself:

"Now, if I can have fine grinding of the gangue and coarse grinding of the metal, I can separate the metal out by its dropping and by the gangue floating." For right there is an interesting principle of physics. When a particle is floating in water, its tendency to sink is determined partly by its weight. The weight tends to carry it down if it is heavier than water. The surface of the particle tends to resist that, tends to keep it up. If the surface is greater, in respect to the weight, it will not go down so fast. If the weight is greater in respect to the surface, it will go down faster. Now, if you imagine a little cube of metal suspended in water, and imagine its linear dimensions doubled in all directions, the surface will have been squared, and that is the thing which resists dropping, while the weight will have been cubed. The weight has increased faster than the surface. Therefore that doubled cube will sink faster through water. That law, of the square as to the surface, resisting sinking, and the cube as to the weight compelling sinking, is the thing that makes big particles drop more in accordance with their true specific gravity, but fine particles like slimes refuse to obey the laws of specific gravity, and continue to float and not sink, whether they be mineral or whether they be metal.

As Dr. Liebmann illustrated on the stand, if the rain came down in a shaft it would kill us all. When the same amount of rain is broken into small drops, it does not kill us. Why? Because the surface has been so enormously increased with respect to the weight, or vice versa the weight diminished with respect to the surface. So the resisting surface makes those drops come down, not like bullets, but gently. And going a step further, when the particles are smaller still, they will not come down at all. They will float like the summer cloud in the sky. Their specific gravity is just as great as it ever was with respect to the air, but they are so small that they are floated.

THE COURT: Is it because they are so small, or is it because of their form?

MR. KENYON: Their form would have a tendency to be spherical in all cases, but it is a function of their size.

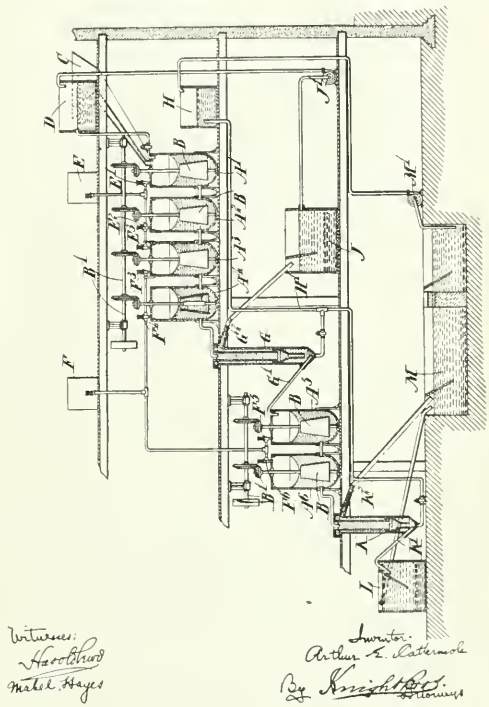
THE COURT: I suppose if you dropped a needle into water and kept it point downward, it would go down fast.

MR. KENYON: Yes, it would go right down. Drop it sidewise, so that you have multiplied the surface without changing the weight, and it will stay right there.

Now, Cattermole conceived this brilliant idea: If I can only make my gangue particles fine, they will stay up there indefinitely. If I can only make my metal particles big, they will drop faster. He knew he could not do that in grinding. Let the inventor of the future, if he be here present, take this for a cue: A grinding machine that at the same time will grind the gangue fine and the metal coarse will revolutionize all these processes. Cattermole knew that could not be done in grinding, so he said: "I will grind it all fine, and then by the gluing effect of oil, particle to particle, oil which goes to metal and does not go to gangue, I will roll and work my metal particles into big metal particles, whereas the gangue will remain as fine as it was ground; and then when I have done that, my big metal particles, my granules, my spherules, will drop and the gangue will go up."

That was the Cattermole idea, and men proposed to do that thing, and these plaintiffs, and the world would have been concentrating their ore by that process today in preference to all others, probably, but that the invention of the first patent in suit was made.

The Cattermole idea of operation was by oil adhesive-



CATTERMOLE'S PATENT.

Reduced facsimile of drawing accompanying A. E. Cattermole's patent, No. 777,273, of December 13, 1904.

ness and mixing. Air entrainment was a trouble. Flotation scum was a loss. Two to five per cent of oil on the ore (4 to 10% on the metal; it was a rich 50% metal ore) was the amount, and if the effects were diminishing, then they increased slightly the amount of oil. (Higgins, Printed Record, p. 212. Q. 43, 44.)

Thereupon a recess was taken until two o'clock p.m. same day.

THE COURT: Mr. Kenyon, I was very much interested in the remark you were making before recess on the matter of the difference between big particles and little particles, in the strength of their power to overcome resistance. Now, entirely aside from surface tension as such, and I mean that sort of tension to enable very minute particles, although having a greater specific gravity than other particles, to float on the surface.

Aside from that, and aside from the case in which the mineral particles having greater specific gravity are attached to any medium of buoyant character which tends to support them, these small particles, if once placed beneath the surface of the water, having greater specific gravity, of course, would sink.

Mr. Kenyon: Yes, and No. The coarsest will sink at once. The finest of them would ultimately sink, but the finest of them would take so long to sink that it is impracticable to separate them or do anything with them by sinking, and that was the slimes problem in all these metallurgical operations. They would float there. They would float in the liquid. When you get down to a certain ultimate point of fineness, whether it be metal or gangue, it will float in the water underneath the surface.

The Court: Underneath the surface?

Mr. Kenyon: Underneath the surface.

The Court: But still they would gradually sink?

Mr. Kenyon: After a long, long time.

The Court: I would like to understand you. Of course, we all know that if we could conceive of a perfect vacuum, both a bullet and a feather will go down together.

Mr. Kenyon: Under the law of their specific gravity absolutely.

The Court: When you come, however, to a resisting medium (I do not care whether it is air or water) then you have a different proposition, and there you have a resistance which has to be overcome, and as you proceed arithmetically the resistance increases geometrically, I believe. Is that right?

Mr. Kenyon: Yes.

The Court: My question is whether these particles would finally sink? I want to get the theory if I can. Aside from surface tension, if you once get those particles underneath the surface of the water, not attached to any bubble or any substance which has a less specific gravity than water, will they not sink, although at a greatly diminished rate?

Mr. Kenyon: It will ultimately sink, although there may be what they call a colloidal condition, which has been somewhat discussed here—clays are very colloidal, and have a tendency to keep them in suspension perhaps for days before they would sink. Even they will, as I understand it, ultimately sink.

The Court: Ultimately?

Mr. Kenyon: The least little jar or agitation will send them right up again. The whole slime problem and difficulty in all metallurgical operations, and in the cyaniding processes as well as concentration processes, turn just on the long length of time it takes the fine particles to settle to the bottom. They will float an inch below, two inches below, three inches below, all around, almost indefinitely, making muddy water.

The Court: The very instant this material passes into a larger mesh and you have a larger particle, it will overcome that resistance?

Mr. Kenyon: Yes, sir, and then the weight increases by the cube, whereas the resistance only increases by the square.

The Court: I see.

Mr. Kenyon: That is the mathematical theory of the whole thing. So, the coarser the grinding the better these water separation processes were, the greater the difference in specific gravity. But what you ran up against there was the fact that in the heart of a grain of gangue there might be a particle of metal, and you have lost it by not grinding fine. So there the millers were between the Devil and the deep sea.

Mr. Kenyon: It has been shown that the processes of the patents in suit depend in part at least upon certain simple facts of physical science that are observable to the knowing eye, and that clearly distinguish them from the prior art. We have shown that these processes are not oil-foam or oil-froth processes, or oil-emulsion processes, or aerated oil-flotation processes in any proper sense, but are processes of air-flotation: processes that effectively evoke the power of air to select out the metal from the gangue in a freely flowing pulp, and to float it to and through the surface for separation.

Air has little affinity for oil as such, and air-bubbles do not readily attach themselves to oil globules, and have slight lifting power when so attached. If a particle of mineral lies entrapped in an oil globule, or has an oil globule attached to it, an air bubble coming in contact with the oil globule will take away a portion of the oil, but will have little tendency to attach itself to the mineral. Therefore, while air bubbles may be mechanically caught and entrapped in oil, and may in that way increase and greatly increase the mass buoyancy of the oil, that is, its power to raise mineral particles that are also caught and entrapped within it, this action of the air (which had been suggested in the oil-foam processes of the prior art) is not secured unless the amount of oil is sufficient and the character of oil suitable to so mechanically embrace and entrap both air and mineral. That is, the oil must be viscous.

Air has a powerful affinity for clean, metallic, sulphide surfaces. This affinity is defeated for all practical ore concentration purposes in the mill when the mineral surfaces are coated with so much oil as to exhibit the physical properties of oil as such, such as adhesion to other similar oiled mineral surfaces, as in the Cattermole process, or adherence to an oil lake or to an oil foam mass and resultant buoyancy flotation, as in the Elmore process, the *California Journal* process, and so forth. But when the film of oil on the metallic surfaces is extremely attenuated (as when 1% of oil to ore is employed) the affinity of air for metal is not merely undefeated; it seems to be positively increased (why, we do not know) so that for all practical ore concentration purposes in the mill the attachment of air to such metal when once attained will persist in and out of the pulp, and will survive any amount of excess agitation or of excess aeration in the pulp.

Air bubbles have vastly greater lifting power for metal particles than oil globules have, and especially the sort of air bubbles that are produced, either by agitation or

by aeration, in water modified by the reagents of the patents in suit.

Air bubbles in unmodified water, however produced, progressively and rapidly coalesce, and with explosive violence, which tends to explain the fact that such air bubbles, namely in unmodified water, will not practically concentrate ore.

Air bubbles in pulp modified by the re-agents of the patents in suit have an enhanced selective affinity for metal over gangue (why, we do not know), and a persistence of life as bubbles in the pulp and a persistence of attachment to contacting metal particles in and out of the pulp sufficient (but why, again, we do not know) to permit in practice of ready separation and removal, and to result thereby in effective ore construction.

THE COURT: You say "Why, we do not know." Is there any theory on that subject?

MR. KENYON: We have presented no theory.

THE COURT: You have no theory?

MR. KENYON: We have no theory. Dr. Sadtler says variation of surface tension explains the phenomenon, but how I do not know. I do not know how variation of surface tension can enhance selective affinity, or how it can explain persistence of life as bubbles in and out of the pulp, or how it can explain persistence of attachment to contacting metal particles in and out of the pulp, to such a degree that practical ore concentration in a mill is an accomplished fact.

Whatever the explanation of the phenomena involved, it is clear that the operation proceeds by contact of air and metal in a freely flowing pulp under circumstances conditioned by the presence of the re-agents of the patents in suit, and opportunity of flotation after contact.

THE COURT: You say the contact between the air and the mineral particles?

MR. KENYON: In the pulp.

THE COURT: Now, if the mineral particle has a film of oil, no matter how thin, how is there any actual physical contact between the air and that particle?

MR. KENYON: The mystery of the thing is that when the oil film of the attenuated character that is produced with one-tenth of 1% of oil to the ore, when that film is present on the metal particle, the air particle has an enhanced appetite for it, seeks it with increased avidity, instead of with diminished or defeated avidity such as a thicker film will produce.

THE COURT: And it seeks it through that very thin film?

MR. KENYON: Seeks it through that very thin film, as it were—that helps.

THE COURT: Not through the actual contact, but through the film being so very attenuated, it seeks the metal particle, and the interposition of the film, far from lessening the selective action of the air for the metal, enhances it—is that right?

MR. KENYON: Yes, that is right, and Dr. Sadtler on the stand suggested an idea that may help a little. He said that an attenuated film of that kind might possibly be conceived of as smoothing the roughness of the surface of cleavage of the sulphide particles.

MR. WILLIAMS: That was Dr. Liebmann.

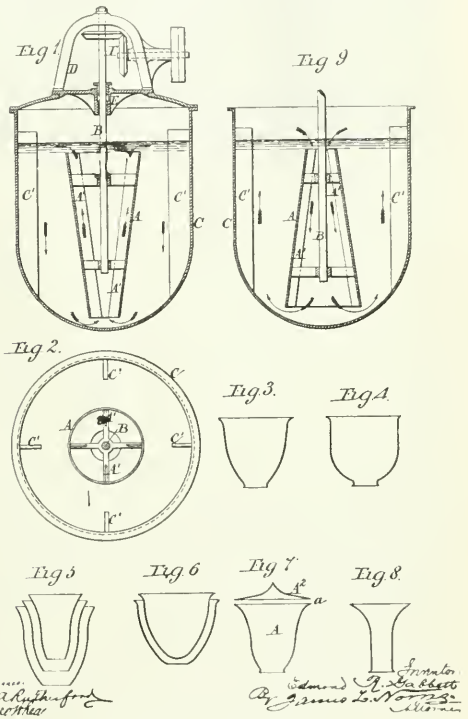
MR. KENYON: Dr. Liebmann?

THE COURT: Increasing the effect?

MR. KENYON: Increasing the attachment or appetite of the air bubble for that surface so smoothed.

MR. WILLIAMS: In fact, they both suggested it.

MR. KENYON: Yes, Dr. Liebmann also suggested that idea; and Mr. Dosenbach, as I remember, said that when these particles had rough surfaces the air bubble would not hold them. It is the smooth surface that the air



THE GABBETT MIXER.

Reduced facsimile of drawing in E. R. Gabbett's patent, No. 444,345, of January 6, 1891.

bubble gets its grip on. Now, this microscopic film of oil may fill up microscopic cavities, may bridge over microscopic roughnesses, may make smooth what was before rough, and in that way enhance the avidity of the air particle for it, and the grip of the air particle upon it; but I present that with diffidence. That is a matter of speculation.

THE COURT: You have the evidence on both sides for that, so I do not suppose counsel on either side will contest it.

MR. KENYON: That is so, but with all respect to both witnesses, I present the suggestion with diffidence.

But now let me state again what are the clear essentials from the point of view of operation, whatever the explanation of phenomena. Whatever the explanation of the phenomena involved, it is clear that the operation

proceeds by the contact of air and metal in a freely flowing pulp under circumstances conditioned by the presence of the reagents of the patents in suit, and opportunity of flotation after contact. You have got to bring your bubble and your metal particle into contact in this freely flowing pulp, and under circumstances conditioned by the presence of the reagents of the patents in suit. But to have brought them into contact—that is not enough. There must be another factor, namely, opportunity of flotation after contact, so that you may separate—flotation up in the pulp and through the surface of the pulp—so that you may practically separate them.

THE COURT: Those are essentials in the flotation.

MR. KENYON: Those are the *sine qua nons,* and those are the only *sine qua nons* if we have presented the proper theory of operation.

And as to apparatus, it is clear, too, that apparatus for efficiently bringing about in a freely flowing pulp the contact of air and metal under the conditions stated, and for permitting or assisting flotation after contact, is all that is required.

It has been shown not only that the fine and slime that were practically unconcentratable in the prior art, except perhaps by Cattermole—I say 'perhaps' because Cattermole never reached the mill. On the threshold of the mill the life of the Cattermole process was cut off by this greater child of the brains of Sulman, Picard, and Ballot.

It has been shown not only that the fine and slime that were practically unconcentratable in the prior art (except perhaps by Cattermole) can be successfully concentrated by the processes in suit, but also that the presence of such fine and slime in the pulp actually assists the concentration of the ore, and is indeed almost essential to practical success; so much so that the art of grinding has been revolutionized where the processes in suit are employed and fine grinding has become the rule, where before it would have been the ruin, of the mill.

The history of what happened in the practical art before the inventions in suit were made, and of what has happened in the practical art since that time, shows that while ways and means of bringing about contact of air and metal in the pulp and of permitting or assisting flotation after contact may be widely varied, the success of the process is sharply conditioned within relatively narrow limits in the matter of the quantity of reagent employed, when that reagent is the oil of the first patent. Especially is this true and crucial in the case of the first patent in suit, since it has been demonstrated beyond dispute that any notable increases of oil above the minute proportion there specified practically defeats the end in view and would in the mill practically prevent the concentration desired, and would be, not only intolerable, as a dirty and utterly non-controllable mill operation, but impossible, as giving at greatly enhanced cost a greatly depleted and inferior product.

Now, why the bubbles have enhanced selective affinity for metal over gangue, and why they have enhanced persistence of life as bubbles in and out of the pulp, no one really knows. No one really understands today why the process works as it does work. Under such circumstances prevision was impossible. And where prevision is impossible, nothing can anticipate except the very thing.

THE COURT: That would indicate that this was a discovery rather than an invention of a process.

MR. KENYON: Yes. It started with a discovery. As a process it became an invention.

Ore-Treatment in Korea

The report of the Oriental Consolidated Mining Co. for the year ended June 30, 1915, is just to hand, and contains the following information on the operation of its mills and cyanide-plants:

Mill.	Stamps.	Ore crushed.	Concentrate saved.	Bullion from ore.
Tabowie	80	117,928	13,719	$407,395
Taracol	80	135,732	12,108	302,319
Kuk San Dong	40	12,790	1,316	27,988
Maibong	40*	26,330	925	210,305
East Candlestick	10	5,109	5,109	33,740
Total	250	297,889	33,177	$981,747

*Part of time.

The average stamp-duty over 230 days was 4.456 tons. The ore assayed $6.55 per ton, and about 50% was recovered in the mills. The concentrate was valued at $780,740, of which $643,571 was extracted as follows:

The Taracol cyanide-plant treated 26,037 tons (including 210 tons of dump re-treatment), with 83.9% recovery, an increase of 1.4%, but at 14c. per ton higher cost; Kuk San Dong, 1398 tons with 54.2%; Kuk San Dong re-treatment, 2837 tons with 73.3%; Candlestick, 5109 tons with 52.5%; and Maibong tube-mill plant (completed late in January), 800 tons with 73.9%, but an average of 88% is expected.

Milling cost 48c. and concentrate 21c. per ton of ore treated ($1.88 per ton of concentrate treated.) The total extraction was 90.3%.

Improvements and re-construction of plants amounted to $140,037.

Dredging in Australia

In Victoria, during 1914, the total quantity of material treated by 45 dredges and 40 hydraulicking plants was 13,979,696 cu. yd., against 16,796,585 yd. in 1913. The gold saved was 56,796 oz., against 65,433 oz. in 1913. The yield per yard was 3.8c., the same as in the previous year. The total area treated was 459.3 acres, the ground varying in depth from 8 to 70 ft. The number of men employed was 1016. Dividends paid amounted to $160,000. Wages and other expenses amounted to about $850,000. The first cost of the plants was approximately $1,570,000. The quantity of tin saved during the year was 45 tons. Satisfactory work in the settling of sludge and stacking of tailing has been carried on throughout the year. In the Bendigo district complaints were investigated where tailing had accumulated in certain water-courses. Wind had blown the tailing, and rain washed it into the water-courses.

TROJAN MILL.

TAILING DAM.

Trojan Ore and Milling Practice

By JESSE SIMMONS

Cyanidation at the plant of the Trojan Mining Co., in the Black Hills of South Dakota does not present any particularly novel features, but the observer will note some refinements and labor-saving devices worthy of mention. The process consists of crushing in cyanide solution in a Chilean mill, the product being divided into 45% sand and 55% slime in classifiers. The sand is given a simple leaching; the slime is reduced to 55% moisture in a thickener, then, after 12 hours of agitation in conical-bottom tanks it receives final treatment in a filter.

MILL-FEED. This consists of that type of auriferous material from the Cambrian measures that has been so happily described as "refractory silicious"*. It is of three general classes, (1) a replaced dolomitic rock of fine texture, (2) a mineralized quartzite, and (3) material from the 'verticals' or mineral-filled fissures and fractures, together with some of the enriched wall-rocks.

It is probable that the gold was originally in combination, in at least a portion of the ore, as sylvanite or a sulpho-telluride; this is indicated by occasional showings of sylvanite in the unoxidized ore deposited on the quartzite. The sylvanite is not, however, of sufficient frequency to form a firm foundation on which to build an indisputable hypothesis; it is to be regarded merely as a suggestion. Pyrite is found throughout this unoxidized ore, all of which, by the way, is shipped to smelters when its gold content is sufficient to bear the expense; otherwise it is left in the mine, since in the cyanide-mill only one-quarter to one-third of the gold is recoverable.

The oxidized ore shows little, if any, pyrite or other metallic mineral, and no free gold can be found by panning. Still there are indications that the gold exists in the native state in an extremely minute, or micro-

*Professional Paper No. 26, U. S. G. S.

COTTAGES FOR EMPLOYEES.

THE JUNCTION.

scopic, form. Probably the fact that over 80% of the recoverable gold is dissolved with ease—entering the solution before the pulp leaves the Chilean mill—is due to its being in almost molecular particles. In contradiction to this theory, the fact is mentioned that amalgamation fails to recover any gold. Still this may not be conclusive; the gold may be so fine, or so coated with oxides of iron, tellurium, or selenium—or all three—that it is not amalgamable.

Evidence suggests that the gold-bearing solutions followed the crevices and fractures until they encountered a stratum of limestone or lime-shale, either of which may have formed an active precipitant. Silica and gold-bearing minerals replaced the alkaline carbonates to form the orebodies. Study of thin sections under the microscope bears out the geologic features exhibited underground. These verticals cut through strata of mud-shale, sandstones, and sand-shale, and sheets of porphyry, for considerable distances, leaving only vague traces of their enriching agency, but, encountering a limy rock, workable ore deposits have been formed.

In general these verticals, or at least the strongest and most persistent, have a north-south course. Others, not so long, strike in various directions. Between the quartzite, or basal member of the Cambrian, which lies unconformably upon the Algonkian schist, and the 'upper ore contact' is a perpendicular distance of fully 500 ft. Verticals of similar characteristics—alike in appearance, composition, strike, etc.,—are found at both horizons. It is readily conceivable that they are of the same series and that development will prove them continuous through the intervening strata. Whether orebodies will be found in this partly developed area would seem to depend mainly upon the existence of strata of limy rock that could have been enriched by the mineralizing solutions. The fact that the verticals do not continue downward into the schist, although they extend upward through the sedimentaries for hundreds of feet, may be construed as evidence of a downward or lateral circulation of the mineralizing solutions.

Porphyritic rocks, presumably of Tertiary age, including rhyolite, trachyte, andesite, and phonolite, have had a bearing undoubtedly upon the formation of the ore. Their coming was accompanied by faulting and breaking of the strata; then also probably the fractures, later to be filled with silicious materials, were formed. It is noted that on the quartzite in the neighborhood of vertical displacements good bodies of ore often are found.

Crusher and Ore-Bins. An ingenious arrangement of three ore-bins with a total capacity of 1000 tons permits all of the ore to be drawn direct over grizzlies spaced at $1\frac{3}{4}$ in. to a No. 5 K Gates crusher, set to crush to $1\frac{3}{4}$-in. These bins are on the side-hill at the rear of the mill, giving them and the crusher a secure foundation. The face of the rear bin is parallel with the slope of the hill; in front are two bins at right angles to it. At the bottom the fronts join to leave a rectangular space about 10 by 12 ft., in the centre of which the crusher is set. The product of the crusher, uniting with the ore that drops through the grizzlies, passes direct to a belt-conveyor and is delivered to the mill-bin. This belt is 110 ft. between centres and carries its load up a 16° incline. The run-of-mine ore contains a large proportion of material fine enough to pass through the grizzlies; the result is that when a gate is opened to draw rock to the crusher the belt is over-loaded until the mass of fine stuff is carried away, after which it easily handles the crushed product. A feeder is to be installed immediately to give the belt a more uniform load. It is believed that this improvement will make it possible to secure a life for the belts considerably above the 70,000 tons they now ordinarily handle. It should make it possible also to secure a more accurate sample at the head of the belt, for at the present time it is probable that the automatic sampler, which deflects the stream discharging from the belt once in $1\frac{1}{2}$ minutes, must fail frequently to secure a fair average of the rush of fine, which, while it amounts probably to 25% of the total ore passing over the belt, consumes but 15 to 20 seconds in discharging from the belt.

Sampling. Against the stream of ore discharging from the belt a sheet-steel baffle is mechanically interposed at intervals of $1\frac{1}{2}$ minutes. This directs the stream for a period of a little more than a second into a chute leading to two sample-bins, each of which has a capacity for the entire amount taken during a day's run. In the evening when the crusher is idle the sample is drawn from its bin over a $\frac{1}{2}$-in. grizzly to a No. 2 Samson jaw-crusher, set to crush to a size corresponding with the grizzly-openings. The fine (through the grizzly) and the crushed products drop to an elevator and are taken to a second bin, in passing to which one-half of the ore is rejected by splitting the stream. The reject drops to the mill-bin. After the entire sample is crushed the grizzly is changed to $\frac{3}{8}$-in., the jaws of the crusher are set to correspond, and the sample is run through the crusher and elevator back to the same bin. This process is continued without changing the grizzly or crusher-opening, until the sample is finally reduced to 100 lb. It is then shoveled over a split-sampler, reduced to a few pounds, dried, and handled in the usual manner. The first sample, taken at the head of the conveyor, contains approximately 2% of the total ore carried by the belt. The mechanical cutting-down of this quantity should give a precise composite of the day's run of the plant, when the feeder is installed to load the belt more evenly. At the present time the automatic sample is low in assay-value, compared with the exact sample it is possible to get, that is, a sample taken at 5-minute intervals throughout the whole 24 hours, across the chute that carries the feed to the Chilean mill. This indicates that the automatic sample fails to secure a correct proportion of the fine—a material higher in assay-value than the coarse hard rock.

Chilean Mill Practice. From the mill-bin the ore passes to a shaking feeder and is spouted, with three to four times its volume of mill-solution, to a 7-ft. Trent Monadnock Chilean mill. Two of these are installed, but as one is sufficient to perform the required duty, the second is kept in reserve, fully repaired and equipped,

for an emergency. These mills run at 31½ r.p.m., about 7 revolutions faster than the manufacturer specifies, but they show no strains, and operate as satisfactorily as could possibly be wished.

However, some changes have been made in construction; for instance, there has been inserted a lock-nut holding the gear against a collar on the vertical drive-shaft and eliminating the wearing-rings. Babbitt is used in recesses cut for it in the step-bearing, doing away with the friction of iron against iron. Down-thrust troubles have been minimized by dressing the bottom of the vertical shaft to a convex form and inserting, in the bottom bearing, a steel 'button,' likewise having a convex surface, upon which the shaft rests. These changes have done away with a great deal of side sway, lost motion, and trouble with keys, key-seats, and wearing rings.

Each mill is driven by a belt direct from a 75-hp. old type Bullock motor; the motor-pulleys are 20 in., and the pulleys on the mills 110 in. diam. This is a change from the previous practice of driving from a line-shaft, and is much more efficient and less troublesome. It is interesting to note that these 75-hp. motors are developing 107 hp. and carrying practically 50% overload with perfect ease.

Unquestionably the most remarkable feature of these mills is their capacity, which is probably not equalled, and surely not exceeded, anywhere. It is the practice to put through one of these Chileans an average of 230 tons daily. A 'rektang' screen with an opening of 0.021 inch is used, giving a product that is 55% slime. This may be considered a remarkably high duty, as the ore cannot be designated soft; still it would not properly be classed as extremely hard material. It is a large day's work.

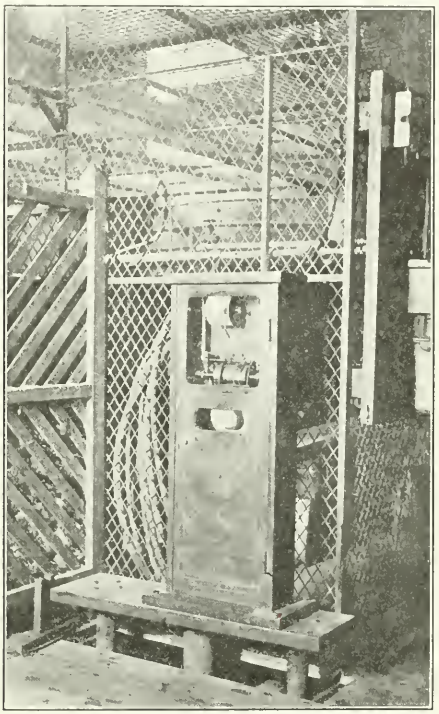
The mills have 4 mullers, each of which when equipped with a new tire, weighs 9000 lb. Tires and dies are made of chrome-steel. Tires crush 26,000 tons before being discarded. Dies weigh, complete, 3400 lb. and have a crushing-duty of 13,000 tons. The thickness of dies and tires is so arranged that a new set of tires will be discarded when the second die is worn out. This reduces to practically a minimum the time necessarily lost for repairs. Beneath the dies are placed 2-in. wooden blocks, raising the die that much above the mortar, and giving a greater screen-area when the die wears thin. This seemingly simple detail makes a decided increase in the efficiency of a mill, and is particularly apparent when the die is worn to 1½ or 1 in. thick.

From the Chilean mills the pulp passes by launder to a bucket-elevator, 37 ft. between centres. The boot of this elevator is of concrete and the housing is sheet-steel. The belt is 18 in. wide: the buckets are 18 in. wide by 6 in. high, of standard pattern.

The elevator discharges into two Dorr duplex classifiers, which divide the pulp into 55% slime and 45% sand. The sand is leached in 6 circular tanks, 28 by 8 ft. The slime flows to a Dorr thickener, operating in a 40 by 14-ft. tank, where the moisture content is reduced to 55%. Part of the effluent solution is precipitated and the remainder pumped to the mill storage-tanks. The underflow from the thickener goes by launder to the agitators—three in number, 17½ by 16 ft., with 30° conical bottoms. After 12 hours' agitation it is washed in a filter and discharged as tailing carrying 9c. of dissolved gold per ton.

The mill-feed averages $4 in gold and 1 oz. silver, per ton. Of the former 75%, and of the latter 35%, is saved. The cost of milling is within a cent or two of $1 per ton.

Future Plans. These include the installation of



SOLUTION METER.

tube-mills for fine grinding, and the raising of the capacity to 500 tons or more daily. This will necessitate a radical change in the cyanide treatment. Sand-leaching will be abolished. The slime will probably first be dewatered in Dorr thickeners, then agitated, diluted with barren solution, thickened, again agitated, thickened, dewatered on a revolving drum-filter to 25% moisture and stacked on the dump. It has been decided also to install for experimental purposes a Holt-Dern chloridizing roaster, with which tests will be made on the blue unoxidized ore. It has been demonstrated that roasting will increase the susceptibility of these ores to cyanidation, but whether this particular kind of a roast will fill the requirements is not known.

Secondary Precipitation. Not the least interesting feature of the property is the tailing-dam and plant, where seepage from the dam is passed through a pre-

cipitating medium. The dam is formed of sand-tailing, which, sluiced from the treatment-tanks, is carried down the gulch in a 6-in. pipe. This pipe has been extended across the gulch, allowing the sand to form an embankment, fully 75 ft. high, that serves to impound the slime. Surface-water is caught above the dam and carried around it in ditches.

A bedrock drain, constructed of concrete, collects the seepage; this is conveyed to the precipitation-house, where are installed 55 tubs, made of whiskey-barrels. After experimentation with charcoal, zinc, and soft-coal clinker, the last was adopted as best suited to the purpose. It is obtained from the Chicago & North-Western Railroad. The idea is to clean the tubs annually and ship the clinker with the slag, matte, and other valuable refuse from the clean-up of the bullion-melting department. A wide variation is noted in the amount of water passing through the plant. In the winter it is as low as 40 to 50 tons daily; in rainy weather in the spring, it often amounts to 1000 tons in the same length of time.

The assay-value likewise has fluctuated between a maximum of 20 cents and a minimum of 4c. per ton. Usually the high content appears in the early spring, when the frost is leaving the ground. Assays indicate a recovery of 75% of the gold on the low-grade waters, and a better precipitation on the high-grade. Since the plant has been in operation for about two years, during which time the tailing has had an opportunity to leach, the gold-content appears to be gradually decreasing. At the present time the maximum is about 10c. and the minimum 4c. per ton. Cyanide and alkali are barely noticeable.

Gasoline Locomotives. Seven-ton gasoline locomotives, made by the Milwaukee Locomotive Mfg. Co. are used on the tramway between mine and mill. The Decorah mine is almost a mile distant from the mill, over a nearly level grade. Midway between the termini mentioned is 'the Junction,' where ore-cars from the Empire and Portland mines are picked up by the locomotive and hauled to the mill. From this point to the mill the grade is level, and a train of 16 two-ton cars is easily hauled. From the Portland and Empire mines to the junction the mine-cars are dropped down inclines by electric-driven hoisting-engines.

All of the supplies for the mill arriving by the railroad, amounting to 50 tons per month, are transferred to tram-cars at the Empire. Lighter rails have been replaced by 30-lb. steel; switches and frogs are of heavy, standard, construction, the whole giving the impression of a thoroughly well-built track of 18-in. gauge. Two locomotives are owned, although ordinarily but one is in service, and that on day-shift only. The second is kept in reserve, in good repair. Each is given an annual overhauling when all worn parts are replaced. All mine-cars are equipped with Hyatt roller-bearings.

Welfare Work. To supply the demand for suitable homes for the employees, the company is erecting modern cottages, each of which is provided with water, electric light, sewage, a bathtub, and a good steel range. A hotel, to provide quarters for the bachelor members of the force, is being built. The school-house, which serves 80 to 90 children, is a model of neatness and reflects the interest the company's officials took in its construction.

The Trojan Mining Company is incorporated under the laws of the state of South Dakota, with one million shares. There are but four or five stockholders, the largest block being held by H. W. Seaman, of Chicago, who is president and takes an active interest in all of the affairs of the corporation. H. S. Vincent is general manager, H. P. Slaughter mine superintendent, Charles E. Ellis mill superintendent, C. E. Dawson engineer and purchasing agent, and W. A. Remer, chief clerk. To all of these I am indebted for courtesies. Each contributed his share to the matter discussed, but none of them suggested that the company was a dividend-payer. Possibly it was modesty that caused them to refrain from mentioning the substantial returns being earned. The Black Hills would be a better mining district if there were more enterprises having the capital and aggressiveness of this company.

Ancient gold mines in East Africa are stated to have been uncovered recently in the Mt. Elgon foot-hills. A correspondent writes to the *South African Mining Journal* to say: "Old mining-tools have been ploughed up on this farm, and the owner recently, in excavating a deep trench, unearthed fragments of enamel-ware kitchen-utensils from hard clay, where they must have been lying for thousands of years. No doubt the early Arabs of Yemen, known in history as the Sabeans, who worked the Zimbabwe goldfields of Mashonaland, found their way down here in ancient times when the world was young; or it may possibly have been the Persians who alternated with the Sabeans in successive waves of colonization for many centuries during the first settlement of the East African coast. Personally, the writer feels confident that we find here traces of the enterprise and daring of the old Sabeans, because some years ago, while traveling in Abyssinia and Arabia, he went into the question very carefully, with the result of being able to prove conclusively from extracts from the works of old Greek, Arabic, and Hebrew authors, in conjunction with local facts, that the ancient goldfields of Ophir were situated in Western Abyssinia, in a district not so very remote from Mount Elgon; and that in these days the Sabeans had caravan-routes stretching right across the continent. Ruwenzori, which they called Jebel Kaf, and the Congo pigmies, were known to them 1000 B. C."

Gold amounting to $1,600,000,000 has been produced by California, but according to an estimate of M. Laur, a French mining engineer, this is less than a quarter of the gold contained in the ridge between the Middle and South Yuba river, which he estimates at $6,000,000,000. Professor Silliman's estimate for the same region was $524,610,000, or less than one-thousandth that of Laur. This is by no means a record difference in estimates. Perhaps the greatest difference yet recorded relates to a gold mine in the wilds of Peru, the ore reserves being estimated by a local engineer at $600,000,000, while a London engineer found the 'ore in sight' at nothing.

Standardizing Rock-Crushing Tests

By M. K. RODGERS

*Reports of rock-crushing tests should include the following details:

1. Description of the machine employed (jaw or gyratory crushers, rolls, stamps, tube-mills, Chilean mills, etc.)

2. Material (timber, concrete, etc.) of foundation. Power is lost in the vibration of poor foundations.

3. Locality, geological, mineralogical, and physical characters of the rock.

4. The power consumption of the machine with no load and full load: the unit being 1 hp. per 24 hours.

5. The capacity of the machine in tons (of 2000 lb.) per 24 hours.

6. The duty in tons per horsepower-day.

7. The screen analysis of feed and product by the proposed A. I. M. E. standard screen-scale.

TOUGHNESS OF ROCK. Table I shows the relative duty of the same machine on three different rocks, all other crushing conditions being the same.

This table indicates that the specific resistance of the rock to crushing, may affect the crushing duty of a unit of power as much as 300%. Perhaps this quality may be called toughness. It is not a function of hardness only. For comparison of tests, rocks should be divided into at least three classes in this respect, determined by the crushing strength per square inch.

SCREENS. For screen analysis, a standard screen-scale, of a uniform ratio between sizes, should be used.

The results of an investigation made by the U. S. Bureau of Standards, with several of the large mining companies, where 240 to 260-mesh screens are used in connection with flotation tests, and including several cement manufacturers and screen manufacturers, are that a screen-analysis for all rock-crushing tests, and practically all testing of materials, will be covered by a screen-scale based on the U. S. Bureau of Standards, 200-mesh screen with a square opening of 0.0029 in. and a wire of 0.0021 in. diameter, advancing with a ratio of 1.414 (the square root of 2, suggested by Rittinger) between the successive sizes of screens, to a square opening of 4.197 in., the area corresponding to 4-mesh; for cases finer than 200 mesh, a 280 mesh or 0.0020 opening, with the above ratio, could be used.

If the analysis is to be carried finer than 0.0029 in. (200 mesh), the next finer sieve-opening in the Screen Scale Series, is 0.002 in. (280 mesh).

*Abstract of paper read at the September meeting of the American Institute of Mining Engineers.

TABLE I.—*Relative Crushing Duty of the same Rock-crushing Machine on Three Different Characters of Rock, all Other Crushing Conditions Being the Same*

Rock and Feed	Mill	Per Cent. Solids	H.p. of Machine	Tons per Machine, 24 hr.	Tons per Hp.-Day	Tons 200 Mesh per Hp.-Day	Screen Scale +4+10+20+40+60+100+200−200							
Calumet & Hecla conglomerate, ¼ mesh.	Conical tube 8 ft. by 30 in.	40	50.0	65	1.30	0.44	Feed	0	65	29	5	1	..	..	..
							Product	..	..	..	3	9	13	41	34
Cœurd'Alêne quartzite, F. M. & S. Co., 5 mm.	Conical tube 8 ft. by 22 in. 28 r.p.m.	43	47.5	112	2.50	0.67	Feed	0	43	43	11	1	1	1	1
							Product	..	..	2	22	18	19	12	27
Miami, ¼ mesh.	Conical tube 8 ft. by 22 in.	27	47.5	229	4.85	1.80	Feed	4	45	33	10	2	2	1	7
							Product	..	..	2	14	12	17	14	38

Relative crushing duty of 1 hp. due to character of ore only:

Calumet & Hecla Conglomerate	1.00
Cœur d'Alêne Quartzite	1.92
Miami	3.75

TABLE II.—*Standard Screen Scale*

Mesh per Linear Inch	Opening, Inches	Opening, Millimeters	Diameter of Wire, Inches	Diameter of Wire, Millimeters	Area of Openings, Square Inches
	4.20	106.60	0.375	9.52	17.64

65	0.0082	0.208	0.0072	0.18	0.0000672
100	0.0058	0.147	0.0042	0.11	0.0000336
150	0.0041	0.104	0.0026	0.07	0.0000168
200	0.0029	0.074	0.0021	0.05	0.0000084

If the analysis is to be carried finer than 0.0029 in. (200 mesh), the next finer sieve-opening in the Screen Scale Series, is 0.002 in. (280 mesh).

Points of View From Lake Superior

By P. B. McDONALD

Lucien Eaton, superintendent for the Cleveland-Cliffs Iron Co. at Ishpeming, has perfected what is called the Eaton-chuck for Leyner drills. This chuck has an anvil-block and does not require lugs on the drill-steel. If the drill-steel gets stuck in a hole, a wrench is used to loosen it. Lugs on drill-steel have always been a nuisance. The Eaton chuck has also been extensively adopted in the Copper Country. Drill-steel for use with it is merely cut squarely and a short hole reamed in the end.

In the Franklin mine, under superintendent Enoch Henderson, some fast driving was done recently. With ordinary working conditions and with no refinements of any kind, three miners per shift, with two No. 18 Leyner-Ingersoll drills mounted on a horizontal bar drove 284 ft. in one month of 26 working days, two shifts per day. Three trammers removed the broken ore to the shaft. A horizontal bar, instead of two columns, was preferred because set-ups could be made over a pile of broken rock and it was not necessary to wait for the tramming; also the bar took less room than the columns and arms. The so-called Leyner cut, utilizing many 'dry' or back-holes, was employed. The rock was the ordinary trap, a tough rock of moderate hardness. According to custom only two-thirds of a shift was worked on Saturday nights. This advance of 284 ft. is said to be a record for the Copper Country. Compared with the advance of 406 ft. of drift made by the Cleveland-Cliffs Iron Co. at its Morris-Lloyd mine near Ishpeming during 26 working-days in May, 1915, this record seems small. But in the iron-mine driving, four miners, six shovelers, and a portable loader were used on each shift, the resultant cost being $10 per foot. The Franklin cost was much lower and was made under ordinary conditions of working.

Mine-managers are doing some figuring as to ore-selection during the period of high prices for copper. These questions, which have been debated so seriously on the Rand, are prominent now at Houghton and Calumet. Is it more profitable to hurry the mining of high-grade ore and sell the greater extraction while prices are up or is it better to hoist a proportion of low-grade ore that could not be utilized at all during other times, for instance, some of the waste lying underground culled from previous years' production? The problem varies for different companies because of such factors as stamp-mill capacity, speed of tramming, and as to whether low-grade ore has to be removed to reach high-grade ore. The Copper Range Co. has pursued a somewhat different policy from most of the other operators, and has not kept its stamps so busy, evidently preferring to handle a smaller quantity of richer ore than other mines where maximum tonnage of ore is hurried to the mills. As to seeking tons of ore production rather than pounds of copper, it is an old story of how bosses on opposite shifts get to competing for the larger tonnage hoisted, and have sent up discarded waste-rock to swell the amount hoisted; in some cases on night-shift there has been even salting of the tops of the loaded ore-cars with better ore to assist in passing inspection or sampling tests.

Thought is being devoted to the hand-picking of copper-ore in the rock-house. Superintendents are asking if the removal of say 10% waste-rock at the mine prevents that quantity of material in the milling processes from 'maliciously' attaching to itself the 5 or 6 lb. of copper which the tailing is known to carry, or whether the waste-rock merely dilutes the tailing without 'grabbing' additional copper in the mill. Experiments are being conducted to determine the efficacy of careful hand-picking in the rock-house, say, by a force of boys working around a revolving circular table where water is sprayed on the crushed ore. The freight expense from the mine to the mill is also a factor of saving.

Hibbing, in Minnesota, one of the pioneer mining towns of the Mesabi range, has a queer condition of affairs. Local politicians with a control of votes have been taxing the mining companies and spending the money in an extravagant manner. Finally the mining companies, of which the U. S. Steel Corporation is one, refused to pay the taxes, and a deadlock ensued. The tax-gatherers threatened to close the mines by process of law, but recognized that if this were done, they would be cutting their nose to spite their face. The city of Hibbing is said to have been spending more money than Duluth, which is many times its size, and to have more street-lights than the city of Cincinnati, even the alleys being lighted to the brilliancy of the Great White Way of New York.

The United States Steel Corporation is trying the experiment of putting bath-tubs in miner's cottages on the Mesabi Range. The company hopes that the miners and their families will use the tubs for baths. In some districts the tubs make handy coal-bins or afford storage capacity for almost any household article, such as pickled pork.

Not much excitement is manifested in the new Kowkash gold rush to the north of Lake Superior in Ontario, although several years ago, several Michigan men achieved fortunes at Cobalt and Porcupine. It is believed that the Kowkash episode is only a small matter, like so many of the recent Ontario rushes. The insignificant gold showings of the Canadian border region across the Minnesota line have tended to discourage interest in the new Kowkash discoveries. It is scarcely believed that there will be another "poor man's camp," like Cobalt, where numerous rich deposits occur in concentrated form close to surface. It is interesting to note that Kowkash is approximately north of Calumet, and not far from the north shore of Lake Superior.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

SECONDARY ENRICHMENT seems to occur more commonly in connection with copper and lead ore.

GREASY MACHINERY may be cleaned quickly by directing against it a jet of steam from the boiler.

STEEL OR CAST-IRON SHOT, or granulations, or defective steel balls, from $\frac{1}{8}$ to $\frac{3}{16}$ inch diameter, are in demand for making bedding for jigs.

MINES of the Coeur d'Alene region are not situated in high rugged mountains, but in smooth-sloped hills at altitudes from 3000 to 4500 feet.

ASSAYS made at the Oriental Consolidated company's Tabowie office in Korea, during the past financial year cost 12.75c. each, on an output of 36,898 assays.

ALTITUDE does not affect men wearing mine-rescue apparatus. Four different types were tried at the top of Pikes Peak, Colorado, a height of 14,147 ft., by the U. S. Bureau of Mines at the end of August.

THE HIGHEST AND LOWEST places in the United States are in Inyo county, California. Mount Whitney is 14,522 ft. above sea-level while Death valley, 50 miles south-east is 300 ft. below sea-level.

PRODUCTS OF MINES supplied 57.22%, or 626,075,666 tons, of the total of 1,094,123,895 tons of all freight carried on railroads in the United States during the fiscal year ended June 30, 1915. The quantity was a slight decrease, but an increase in proportion.

PORTLAND CEMENT is made by mixing in proper proportions calcium carbonate and clay, which are heated to expel moisture. The mixture is pulverized and calcined at a high temperature to produce the so-called clinker, which is ground to pass a screen of 100-mesh.

THE POWER-PLANT at the Ford Motor Co.'s factory at Detroit is a combination of a producer-gas engine and a steam-engine, the exhaust gases from the gas-engine being used to jacket the steam-engine cylinders, and the exhaust from the steam-engine being used to assist in scavenging the gas-engine cylinder.

BEST RESULTS are obtained from wire rope with large size sheaves and drums; their use is strongly recommended. It is important that grooves be smooth and of sufficient size so that the rope fits easily, without wedging or bending on the side. When a groove becomes scored, it should be turned to eliminate the corrugations. If this is not done, shortened rope service will be the result, because of excessive wear on account of the rough surface. Another important factor is the keeping of drums and sheaves in alignment, otherwise there will be undue wear on the rope as well as on the sides of sheaves and drums.

WHETHER the formula H_2O applies to ice, liquid water, or to steam, was a question given to candidates for teacherships in high schools where chemistry is taught. Reasons for the answer were required. It is said that the effect of this innocent query on those being examined, university and technical school graduates mainly, was appalling.

ONE SEEKING to initiate a claim to mining premises legally located by another has the burden of proving that the annual labor thereon has not been performed, and thus establishing that the claim is ground subject to location. Copies of 'non-contribution' notices are admissible as evidence that work and labor on the claim have been performed in the past.

A LOCATOR of oil-lands, who has made his location and remains in possession, has a good title as against anyone but the United States. One who leases from such a locator under covenant that the locator has fee simple title cannot rescind the contract and recover consideration paid on the grounds that such a title is not fee simple, without first restoring to the locator such title as the latter had by relinquishing or returning the lease.

MAGNESITE PRODUCTS are giving satisfactory results, and are growing in popularity. It has most of the qualities necessary for floors, such as cleanliness (sanitary qualities), quietness, immunity from abrasion (surface wear), resilience, immunity from slipperiness, appearance, water-proof, plasticity, warmth (thermal insulation), life (immunity from deterioration with age), acid-proof, alkali-proof, fire resistance, elasticity, crushing strength, structural strength (rupture), immunity from expansion and contraction, and lightness.

MORE MEN are killed in metal mining in the United States, in proportion to the number employed, than in the country's coal mines. It has been the custom to consider American coal mining as dangerous, because of accidents in which hundreds were killed at one time, but in metal mining a great number of small fatal accidents take place frequently. The fatalities per thousand men employed for three years are here given.

	1911.	1912.	1913.	Three-year average.
Coal mines	3.73	3.27	3.82	3.60
Metal mines	4.45	4.09	3.72	4.08

Evidently 'safety-first' precautions had a beneficial effect on metal-mine accidents in 1913, the rate being 3.72 as compared with 4.09 and 4.45, respectively, in the previous two years.

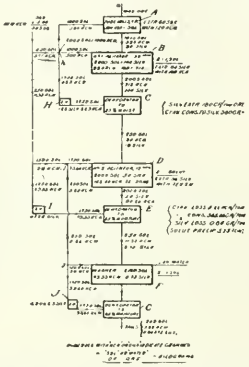
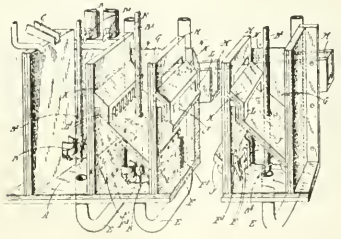
1,156,382. Process of Extracting Metals from Ores. Robert S. Towne, New York, and Cyrus Robinson, Mount Vernon, New York, assignors to Metallurgical Engineering & Process Corporation, a corporation of New York. Filed July 14, 1910. Renewed March 8, 1915.



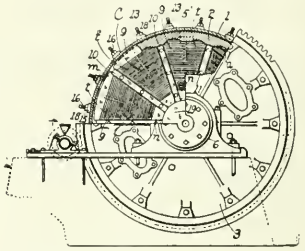
1. The herein described process for effecting the separation of soluble values from a mass, it consisting in subjecting the mass to the action of a solvent solution of comparatively high dissolving efficiency for a comparatively short period of time, positively and actively agitating the mass and the solution during the said period, subjecting the mass to a positive and active dehydration, thereby withdrawing from it a major portion of the solution together with the dissolved values contained therein, subjecting the remaining mass to the action of a similar solvent solution of comparatively low dissolving efficiency for a comparatively long period of time, positively and actively agitating the mass and the solution during the said period, subjecting the mass to a second positive and active dehydration thereby withdrawing from it a major portion of the second solution together with the dissolved values contained therein, and extracting the dissolved values from each of the said withdrawn solutions independently of the other.

1,155,815.—Apparatus for Ore Concentration. Arthur Howard Higgins and William Warwick Stenning, London, England, assignors to Minerals Separation, Limited, London, England. Filed November 12, 1913.



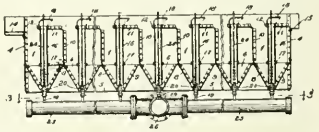
1. Apparatus for concentrating ores by gaseous flotation of certain mineral particles in liquid comprising, in combination, a vessel, means for introducing a gas therein at the lower part of the vessel, means for producing a zone of violent agitation and gasification in the lower part of the vessel, a baffle above the agitator for producing a quiescent zone in the upper part of the vessel, the baffle being inclined downwardly from the inlet side to the outlet side of the vessel, an inlet for the pulp to the vessel below the baffle, means for removing the froth from the upper surface of the liquid, and an outlet for the residues above the baffle.

1,152,239. Ball-Mill. Frank E. Marcy, Salt Lake City, Utah. Filed March 3, 1915.



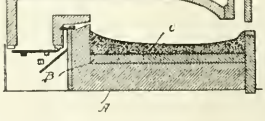
1. In combination with a drum rotatable about a fixed axis and provided with terminal heads having openings respectively for the feed and discharge of the material, a series of radial blades or lifters disposed on the inner surface of one of the heads, grate sectors having contiguous edges resting on the inner edges of the blades, and means engaging the edges of the sectors for securing the sectors to the blades.

1,156,372.—Agitator for Ore Treatment. Cyrus Robinson, Mount Vernon, New York, assignor to Metallurgical Engineering Process Corporation, a corporation of New York.



1. In an agitator for ore treatment, the combination of a receptacle adapted to contain a mixture of solvent solution and finely divided ore, a vertical tube mounted in the receptacle and terminating at its lower end above the bottom of the receptacle, an air nozzle at the bottom of the receptacle below and closely adjacent the lower end of the tube, means for delivering air to the nozzle to agitate the mixture in the tube and force it upward therethrough, means supplemental to the receptacle for receiving the mixture from the upper end of the tube, and means for entering the nozzle to cut down the effective cross area thereof.

1,155,628.—Method for the Treatment of Zinc Ore or Zinc-Bearing Material. Sewall Truax, Canon City, Colorado, assignor to Granadena Mining Co., a corporation of Arizona. Filed Dec. 16, 1910.

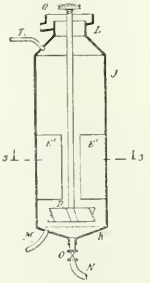


1. The herein described method of treating slag containing zinc comprising maintaining the slag in a fluid condition in

contact with a body of finely divided reducing material, the particles of which are prevented from passing into the fluid.

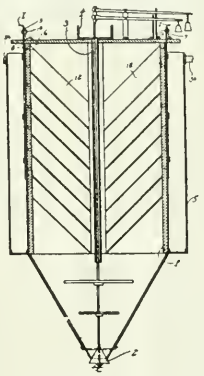
2. The herein described method of treating slag containing zinc comprising melting the slag, depositing the fluid on a solid body of finely divided carbon reducing material and a binder that prevents the particles of reducing material from passing into the fluid, and maintaining the slag in fluid condition.

1,155,836.—Apparatus for the Concentration of Ores. Thomas Mackellar Owen, Broken Hill, New South Wales, Australia, assignor to Minerals Separation American Syndicate (1913) Limited, London, England, Filed May 2, 1914.



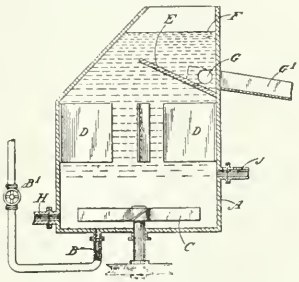
1. In an apparatus for concentrating ores by gaseous flotation of certain mineral particles in liquid, a single upright vessel open at the top comprising both an agitation and a separation vessel, an inlet conduit for ore pulp at the bottom of the vessel, an outlet conduit for tailings near the top of the vessel, a rotatable agitator in the lower part of the vessel, a conduit for air leading into the lower part of the vessel, vertically elongated baffles immediately above the agitator terminating at a substantial distance below the surface of the liquid in the vessel for producing a baffling zone above the atomizing zone and a substantially quiescent topmost and separating zone above the baffling zone.

1,156,276.—Slime-Thickener for Dewatering Mine-Tailings. Wilton E. Darrow, Sutter Creek, California. Filed February 8, 1915.



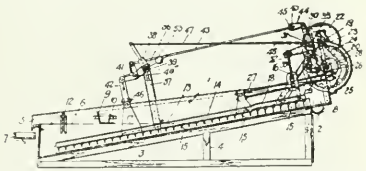
1. A device of the character described comprising a receptacle having a central inlet pipe extending to a point near the bottom thereof, a plurality of openings in the side of said receptacle, another receptacle disposed around said first named receptacle, said openings communicating with said second named receptacle, and a plurality of deflectors arranged in said first named receptacle, as described.

1,155,861.—Ore Concentration. Louis Albert Wood, London, England, assignor to Minerals Separation American Syndicate (1913) Limited, London, England. Filed June 2, 1914.



1. A process of concentrating ores which consists in subjecting the powdered ore suspended in water free from frothing agents to the admission of gas, forcefully disseminating the gas through the pulp in such a way that the gaseous bubbles preferentially attach themselves to certain mineral particles and rise toward the surface and discharge their mineral load with the pulp, and catching and removing such discarded mineral below the surface of the liquid.

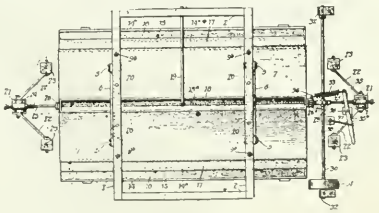
1,156,543.—Ore-Classifier. David J. Nevill, Denver, Colorado, assignor to The Dorr Cyanide Machinery Co., Denver Colorado, a corporation. Filed January 28, 1913.



1. In apparatus of the character described, a reciprocating rake having a pair of slotted hangers, and means for movably suspending said rake, including a pivotally mounted yoke extending loosely in the slots of said hangers.

2. In apparatus of the character described, a three-armed lever, a bell-crank operatively connected with one of said arms, a rake movably suspended from said bell-crank and another arm of said lever, mechanism for imparting a reciprocating movement to said rake, and a cam co-operative with said mechanism for engagement with the third arm of said lever to move the latter about its fulcrum at determinate points in said movement.

1,148,591. Ore-Concentrator. Orrin H. King, Wallace, Idaho. Filed August 2, 1912.



1. In an ore concentrator, the combination of a concentrating table which is suspended and arranged to have a slight endwise movement, abutments against which the ends of the table are adapted to strike, yielding means for normally holding the table in one end position against one of the abutments, and means for jarring and oscillating the table.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

Tin Situation in Cornwall.—Sales at Redruth.—Tailing Treatment and Results.—Sale of an Old Estate.

The tin mines in Cornwall have a hard fight for existence nowadays. For many years the best miners have emigrated, and the proportion of capable hardworking men at the home mines has been comparatively small. Since the War began a great number of these capable men have joined the army, and the mines have been faced by a grave labor shortage. There is no boom in the metal for war purposes, the price remaining at a much lower figure than has been ruling in recent years. As the mines get deeper, the grade of the ore becomes poorer, and no bonanza shoots, locally called 'carbonas,' are found nowadays. Levant, the celebrated mine near Land's End, where the old manager used to delight to hocus his teetotal visitor's ginger-beer with gin, is on the verge of discontinuance. Francis Oats, of De Beers, and his son Freethy Oats, have spent much money and devoted much time to the resuscitation of this mine, but the owners of the mineral rights are making themselves obnoxious by their ridiculous terms in connection with a renewal of the lease, so that Freethy Oats has, without reservation, publicly stated that he is tired of the whole thing. If operations are suspended, the miners will find occupation elsewhere without any trouble, but the little community, other than the miners, will be hard hit, and a district that is bleak enough at any time will become still bleaker.

The fortnightly sales at the Redruth ticketings show a great fall in the amount of tin concentrate offered. On the reduced scale to which we have been accustomed for many years, these sales averaged 250 tons, and this figure was considered the irreducible minimum. The quantity is now still lower, having declined to about 150 tons. Dolcoath and Carn Brea & Tincroft both show decreases on account of the difficulty of finding ore of profitable grade. On the other hand, South Crofty continues to do excellent work, and recent developments at East Pool have been encouraging.

The companies formed to re-treat old tailing are not prosperous. The Cornwall Tailings Co., which treats the dumps at Carn Brea & Tincroft, extracts only 27% of the tin present as indicated by chemical assay. It is a comparatively big producer, selling a great deal more concentrate than most of the mines. During the past twelve months 144,460 tons yielded 432 tons of concentrate, but owing to the low price of the metal no divisible profit was made. The company was formed by an Australian group connected with the Broken Hill South and British Broken Hill companies. The managing director, Arthur Richards, is an engineer who has devoted a great deal of study to chemical methods of extracting tin from ores, so far in vain. The fact that only 27% can be obtained by water concentration helps to prove the contention that both old or new methods and plans have reached the limit of their efficiency. Cyanide came to the rescue of gold ores, and flotation to sulphides of other metals, but so far nothing has been found to supplement the older practice with tin.——Another company, more recently formed for the purpose of beneficiating old tin tailing, is the Carnon Valley Co. This is in the hands of the same group as the Cornwall Tailings Co., but has the additional advantage of the help and advice of Theodore Hoover, who is chairman of the company. The tailing is pumped from the river-bed to a re-grinding and concentration plant. Operations were started early this year, but were suspended after a run of four months. The scarcity of labor and the low price of tin combined to make the work unprofitable. But in addition to these drawbacks, the company has experienced much discomfort with regard to ancient rights and possession of property, and this circumstance played a large part in the decision to stop work for a time. I regret to say that the attitude of Cornishmen toward outsiders in matters of this kind is notorious.——A third tailing company of recent formation is the Cornish Tin Sands, the object of which was to re-treat the tailing on Gwithian beach, where material brought by the Red river from Camborne district is discharged. An extensive plant has been erected here, but more capital was required just about the time the War started, so there was no option but to close. The company is in debt, and will probably have to submit to compulsory liquidation, as a firm that supplied some of the machinery is a pressing debtor.

The most notable event in Cornwall at present is the sale of the Tehidy estate by Mr. A. F. Basset. This estate includes much property in the Camborne and Redruth districts and holds the mineral rights to many of the mines, including Dolcoath, South Crofty, East Pool, and part of Carn Brea & Tincroft. Many a time rumor has had it that Mr. Basset had parted with his possessions, which have been in the family for 800 years. On many occasions some sort of preliminary negotiations have been made on the part of mining companies with the idea of purchasing royalties outright. This time the news is really true, the purchaser being Robert Hamilton Edwards, who has earned fame and made money in the newspaper world as managing director of the Amalgamated Press, the Harmsworth organization owning popular monthly and weekly publications. The negotiations were conducted by Herbert Thomas, known by Cornish miners everywhere as the proprietor and editor of *The Cornish Post*. We believe that it was Mr. Thomas who suggested the purchase to Mr. Edwards. We may be sure that these two gentlemen will be more sympathetic to the mining industry than Mr. Basset, whose heart is about as hard as Cornish ore when mining deals are under consideration. Since Dolcoath was taken over by the present limited liability company 20 years ago, Mr. Basset has drawn £170,000 as dues. Mr. Edwards has indicated his intention of providing a big share of the capital required for sinking below the present depth, 3300 ft., where developments are extremely disappointing, on the off-chance of finding ore again. He has also announced that negotiations for the sale of mining rights will be invited and reasonable terms entertained. All Cornwall is looking forward with unusual interest to such benefits as may accrue from this transfer of the proprietorship of the Tehidy estate.

JOPLIN, MISSOURI

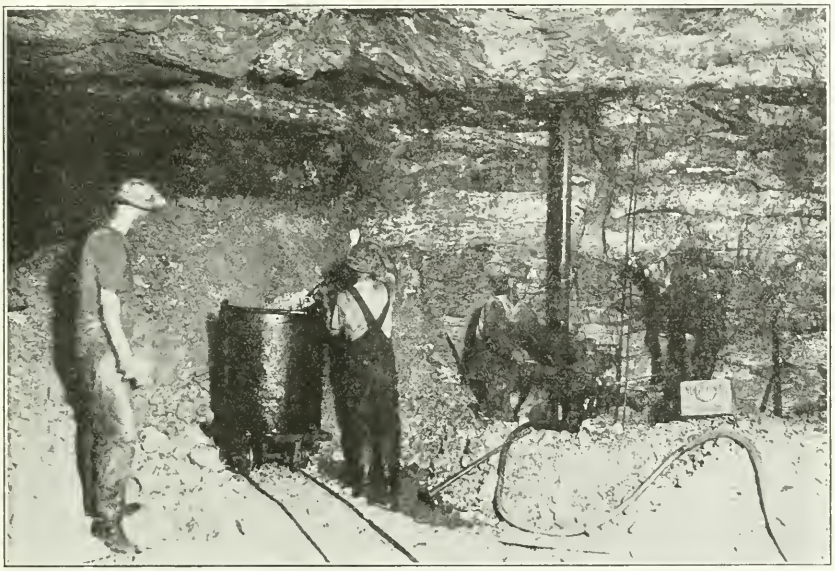
Importance of Sheet-Ground Development.—Mill-Building Activity is Unabated.—District's Largest Plant.—Zinc and Lead Notes.

Nothing could go further toward proving the importance of sheet-ground mining than the continued high prices for zinc ore. With zinc-blende selling at $75 to $85 per ton, basis of 60%, at the beginning of November, compared with a basis price of $40 to $44 at the beginning of that month of 1914, it can be seen that conditions are now much more favorable for the mine operator than they were a year ago. At present

prices, which give every promise of remaining firm for an indefinite period, handsome profits are to be made from zinc mining. At the prices that prevailed a year ago many sheet-ground mines were forced to close. It is true that in periods of low prices more attention, relatively, is given to the soft-ground mines, where the ore deposits are much richer, if not as extensive, than those of the sheet-ground properties; but with strong prices, like the ones that now prevail, the greatest profits are being reaped from the sheet-ground mines for the reason that while the profit per ton from the soft-ground mine may be much greater, the greatly increased tonnage from the sheet-ground mine more than offsets this feature. In sheet-ground development, a view of which is given in the accompanying picture, great areas of ground are cut out, supports being left at intervals depending on the character of the ground. The heaviest sheet-ground production is from the Webb City, Carterville, Porto Rico, Prosperity, and Duenweg, where the average depth of the orebodies is 200 ft. Faces ranging in height from 12 to 20 ft. are carried, and the mill recovery usually runs about 2½ to 3%, about 75% of which is blende, and 25% galena. Because of the opportunities afforded for profitable development in the sheet-ground areas more than a dozen large new plants have recently been constructed and many others are planned. In some instances the average richness of the ground is higher than 3%. In an isolated case or two a recovery of 6 or 7% has been maintained for a year or two at a time, but such instances are rare. In soft-ground mining, on the other hand, as high as 20 or 30% recovery is made, such yields, as a rule, being kept up for only a short time. An average recovery of 10% in soft-ground mining is considered good.

On a 20-acre lease of the Cornfield tract, first lease on which is held by the Zinc Corporation of Missouri, A. F. Dexter and associates have drained the old Century and Herald mines which were flooded in 1905, and which have not been worked since then, and let a contract for the erection of a 300-ton concentrating-plant to be operated by gas-engines. This land is a short distance south of Carterville. The lease lies south of the Luscombe property, and north of the new Kirkwood mill, which has reported a recovery of 5% since it started in operation several months ago. At the Dexter mine, both the old shafts will be worked. Where each of these shafts was equipped with a mill in 1905, one mill will now answer the purpose. Mining will be done at a depth of 165 to 185 ft., a big body of disseminated ore having been blocked out. Day and night shifts are to be worked in construction of the new plant, which will be equipped with new and modern machinery throughout.

On a 15-acre lease of the Missouri Zinc Fields land, south of Carterville, a contract has been let by the Ben Franklin Mining Co. for the construction of a concentrating-plant of 300-ton capacity. Recently this lease was purchased by the Ben Franklin Co. from Burns and others, who developed it. Work on the property, which is in the vicinity of some big-producing mines, shows an almost continuous body of zinc and lead ore from a depth of 155 to 200 ft. The upper part of the orebody lies in disseminated formation, which gradually blends with the sheet-ground formation, where it will be possible to carry a face about 15 ft. in height. All possible haste is to be made in the erection of this mill.



HEADING IN A SHEET-GROUND MINE, JOPLIN DISTRICT, MISSOURI.

Fast mill construction is to be started by Mattes Bros., who recently purchased from John Carey his lease of 15 acres on the Zinc Corporation of Missouri land, south of Carterville. A 300-ton plant will be erected. Tom Tarr will be in charge of building the mill. The land attracted a good deal of attention about a year ago, following several drill discoveries made by Carey, which showed ore from a depth of 135 to 200 ft. As is the case in other mines in this immediate vicinity, the upper portion of the orebody is of disseminated character with an underlying stratum of sheet-ground. Following the drill-holes, two large shafts were sunk, and both of these are now in ore, and driving has been started. Several drill-holes indicate that the orebody is extensive.

Work on the construction of a 150-ton tailing mill was started by G. Kusterer early in November, the material to be procured from several old tailing heaps on the lands of the South Carterville Mining Co., and the Ealor Mining Co. Great dumps of tailing accumulated there from early-day operations.

and assays show they contain enough zinc to make their treatment profitable.

Ben F. Wurzell and associates sold for $9000 their Sophia mine on the Budd M. Robinson land at Belville, north-west of Joplin, to the Emily Mining Co. The lease has a mill of 75-ton daily capacity.

At Granby, Missouri, the district's largest plant, the Klondike, is now in operation. It can handle 500 tons of ore per shift, and is receiving its ore supply from two shafts, which are 225 ft. deep. An extensive body of disseminated ore, 25 ft. thick, is blocked out with drill-holes and drifts. Electric power is used to drive the mill, hoists, and pumps.

That it is difficult to say just when a mine is worked out is shown at the properties of the Bradley Lead & Zinc Co. No. 1, and the Dutchman's Choice Mining Co. Both these mines are equipped with large concentrating-plants, and are situated on a tract of the St. Louis-Joplin Lead & Zinc Co.'s land at Chitwood, north-west of Joplin, where the old A. B. C. mine was worked. It was generally thought that the most of the ore had been worked out by the A. B. C. Co., the mill of which was burned several years ago. The new companies, however, are making large 'turn-ins,' the Bradley's production being especially noticeable, its output in a single week being 103 tons.

TIMMINS, ONTARIO

Further Discoveries Near Kowkash.—Plenaurum and Davidson Mines.

Besides the King-Dodds property at Kowkash, two discoveries have been reported from Tasliota lake, 20 miles west of Kowkash, and one mile north of mile-post 63 on the T. C. railroad. On one of the claims staked by Messrs. Devaney, Conners, and Morrison, a vein has been traced about 300 ft., averaging three feet in width, on which three samples have been taken yielding $8, $14.80, and $19.20 per ton; other samples gave as high as $62 per ton. In this vein free gold has been found associated with a steel-gray mineral, which proved on roasting to be a telluride compound. Qualitative tests on the same ore showed the presence of gold, silver, and lead, associated with tellurium.

Concerning the discovery on the Brennan claims at Tashota lake, and that on the Boyle claim at O'Sullivan lake, there are many rumors, but nothing definite is obtainable. An amusing feature of this rush is that at least one claim has been staked on an old diamond-drill hole, of which several have been found in this district.

It is reported on good authority that negotiations are proceeding between the La Rose interests and the owners of the Plenaurum, with a view to purchasing the latter, and work is about to commence preparing the Plenaurum for sampling. This, with the termination of the suit against the McIntyre Extension, and the control of the Jupiter by the McIntyre interests, will make the area north of Pearl lake active again in the near future.

The de-watering of the shaft in the Davidson claims at North Tisdale has commenced; negotiations are proceeding for the purchase of the Dohie claims in Deloro township, and the Success gold mines are being sampled by Auburn, New York, interests with a view to purchase.

TORONTO, ONTARIO

Work at the Principal Cobalt Properties.—Kowkash.—Miners' Strike.

Shipments of bullion from Cobalt continue light, as some leading producers prefer to store their output, hoping that there will be an improvement in the market. The statement of the Nipissing company on October 20 shows cash in hand $772,556, bullion in transit, $183,200; and ore in process and bullion ready for shipment $513,418; making total quick assets $1,460,174. The payment of the latest dividend brings the total disbursements to stockholders up to $13,440,000, or over twice the amount of the capital. R. B. Watson, general manager of the Nipissing, and party have returned from Le Pas in northern Manitoba, where they have been inspecting a rich discovery made by Jack Hamel, with a view to its purchase. No decision will be arrived at until careful sampling has been done.——Developments at the 385-ft. level of the Cobalt Lake property adjoining, disclosing ore of good width and grade, indicate that a large orebody on the Nipissing side of the boundary will be available.——The Coniagas has passed the dividend usually paid on November 1, the reason being that owing to the low price of silver the management has considered it advisable to curtail the output.——The spectacular 'silver sidewalk,' which attracted so much attention in the early days of Cobalt, has been sold by the La Rose Consolidated to the Ontario government, which will preserve the richest portion of it intact, as far as possible. It is now being carefully removed. Instead of blasting it, holes are drilled beneath it, which are filled with unslaked lime, and water poured in. The slaking of the lime will loosen the section to be taken out.——The Trethewey Mining Co. is operating the Rochester property from the 300-ft. level of the Lumsden, and has cut some patches of high-grade ore.—Another old-time producer which is being again worked is the Silver Queen, from which high-grade ore is being extracted.——The Crown Reserve has taken charge of the Globe Consolidated near Weaverville, Trinity county, California. It will spend $50,000, to be repaid out of gross ore receipts, taking 60% until the amount is paid off. Afterward the profits will go to liquidate outstanding liabilities amounting to about $253,000. For this assistance the Globe gives the Crown Reserve a 55% interest on a 30 years' lease.——The Temiskaming has cut a 5-in. vein of high-grade ore.——The Davidson property near Porcupine has been optioned to a Toronto syndicate, headed by Alex. Fasken, and is being unwatered.——At the North Thompson a high-grade vein was cut on the 200-ft. level, which, on being followed, widened to 23 ft., with ore of increased value.

Further discoveries in the Kowkash field are continually reported. Several wide dikes have been uncovered, showing rich ore on the surface. Tellurides have been found in several places. Many buildings are being erected, and a road eight miles long is being built from the King Dodd claims to Kowkash station, so that machinery can be brought in. The field has extended to Tashota, about 15 miles south-west of the King Dodds property, where many claims have been located. There is a regular Pullman car service in operation between Toronto and Kowkash, and the railway traffic is heavy.

The short-lived strike, involving about 2500 men employed in the asbestos mines around Thetford Mines, Quebec, occurred on October 18. Wages were reduced on the outbreak of the War on account of the weakness of the market, and the men asked that as conditions had improved the old rate be restored. They also demanded the abolition of the truck system, under which employees were compelled to trade at the stores of the companies. These demands were agreed to, and work was resumed on the 2nd.

In a circular sent to shareholders of the Dome Lake Mining Co. the directors state that recent developments have been favorable, and costs have been reduced. Production to August 31 was bullion worth $63,738, and concentrate valued at $9776 net from 9318 tons of ore. A cyanide-plant is necessary for better recovery of bullion. Stoping cost $4.13 per ton; driving, $12.30 per foot; sinking shaft, $49.93 per foot; sinking winze, $40.70 per foot; tramming, hoisting, etc., $1.31 per ton; and total mine operating costs, $3.90 per ton.

At the west end of the Chambers-Ferland mine three drills are at work. To cut the extension of one of the Nipissing veins cross-cutting is under way on the 275-ft. level. Two faults cross the Nipissing near the boundary, so exploration is rendered more difficult. Twenty-five men are employed in charge of J. A. McVichie.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Road construction in this region was finished for the season last month. The Marconi Wireless Telegraph Co. may extend its all-night service to Fairbanks. Juneau has this service already.

It is estimated that the gold output of Circle this season was $300,000, of which the Berry dredge yielded $75,000.

It is reported that property in the Poorman Creek district, near Ruby, has been sold to B. Walker for $75,000.

Juneau

The Jualin Mines Co. will continue development through the winter, with H. G. Young in charge. Belgians control this property, headed by Jean Vanophem of Brussels, who was recently at Juneau.

At the Gastineau mill 6000 tons of ore is being treated daily. Costs of mining, milling, etc., are said to be 60c. per ton, against 75c., the original estimate.

ARIZONA

The utilization of the rare minerals and the non-metallics in Arizona is one of the first problems to be considered by the State Bureau of Mines at Tucson. The metallurgist of the Station, P. E. Joseph, is in charge of these investigations, which will be promoted by free publications that will be of great assistance to those interested in the mining industry. The first bulletin will be on manganese.

Cochise County

At Tombstone the Bunker Hill Mining Co. is busy with development and testing the ore.

Greenlee County

Recent events in the strike zone are as follows:

An arbitration board of five members has been suggested as a means of settling the dispute at Clifton. Strike leaders received the idea favorably. The militia has been increased.

The Secretary of the Department of Labor at Washington, D. C., has sent a commission to Clifton to investigate the strike.

Pascasio Heriz, a Catholic priest at Morenci, was forced to leave the district for his alleged anti-Western Federation remarks. The attorney for the Arizona Copper Co., W. C. McFarland, was also compelled to leave.

A levy of $1 to $2 per member has been voted by the Western Federation of Miners to help the strikers.

Yavapai County

For some months the United Verde Extension has been shipping 35 tons of ore per day, yielding a total net return from the smelter of $350,000. The current year's net will be about $500,000. Additional equipment will enable an output of 150 tons per day early in December. The new electric hoist has a capacity of 1000 tons per day. A 1200-ton storage-bin, and track to connect with the United Verde Copper Co.'s line that goes to the smelter at Clarkdale, are being constructed. If copper remains at its present price the Extension is estimated to earn $1,600,000 next year.

STRIKE MEETING IN THE PLAZA AT MORENCI.

CALIFORNIA

Butte County

Near Forbestown, the Zenith Iron Mine Co., consisting of Oakland people with L. A. Driesbach as president, is developing and extracting high-grade chrome-iron ore, which is being shipped over the Western Pacific line to the U. S. Steel Corporation at Pittsburg, Pa.

Money has been obtained to develop the South Banner company's property near Oroville. R. Phillips is in charge.

——At 300 ft. depth in the Lava Bluff mine, 20 miles northeast of Stirling City, coarse gold has been found. Owing to snow work cannot be conducted in the winter.

Inyo County

(Special Correspondence.)—The Lietzow Consolidated Mines Co. of California was incorporated on August 25 with a capital of 250,000 shares at $1 par. Improvements costing $8000 have been made on the mill-site near the San Pedro, Los Angeles, and Salt Lake line. An incline shaft has been started, also an open-cut. Ore is on the dump for shipment; it assays from $12 to $20 per ton.

Crucero, October 25.

The Skidoo Mines Co. is installing a small oil-fired boiler for heating cyanide solutions, to try and keep the leaching-plant working through the winter. Until development gives better results the 40-hp. gas-engine will not be installed.

Kern County

(Special Correspondence.)—Scheelite concentrates from the 'stringer' district are increasing in quantity. Purchasers of this product who are buying in small lots and paying cash are said to have "struck a snag" in shipments designed for Eastern markets. It is claimed that in less than carload lots, *via* the Santa Fe, (which would mean 40 to 50 tons worth about $60,000), the product must be forwarded by express. One indignant shipper is accordingly sending his by automobile to Los Angeles, bringing back suppiles on the return trip, saving time and money. The express rate is said to be $119 per ton.

Two electric motors, of 125 and 50-hp. respectively are being installed at Goler switch, by the Velmedith Mines Co., for pumping water from three 20-in. drilled wells. These wells are said to be able to provide water for the double purpose of placer mining at old Goler, and irrigating a farming tract near Garlock and Cow Wells.

The 2-in. pipe-line to Atolia from the Consolidated Mines will convey 20,000 gal. of water daily. Electric pumps will force the supply into a large tank on the divide over Rand hill, elevating it fully 600 ft. From the tank a gravity flow of 520 ft. will convey the water to the New Atolia mill.

Randsburg, October 28.

Nevada County

(Special Correspondence.)—Arrangements have been made for the installation of a hoist and pumping-plant at the California-West Point mine, to replace the works destroyed by fire last spring. New York capital is interested. E. S. De Golyer is superintendent. The property is in the Deadman Flat district, four miles below Grass Valley. Several properties in the district are active, including the Normandie and Kenosha.

Kansas people have become more heavily interested in the Black Bear mine, at Rough and Ready, and a 2c. assessment has been levied to finance more extensive work. Several improvements will be made to the mill and mine plant, and an endeavor made to recover the shoot of rich ore formerly worked. William Buchholz is superintendent.

A gasoline engine has been installed at the Union mine, near Banner mountain, and pipe-line placed for water supply to the hoisting-plant. Within two weeks the pumps will start unwatering the incline shaft, which is being cleaned out and retimbered to water-level. An option has been taken on the property by Los Angeles people, and an examination will be made shortly by J. Nelson Nevius.

The county assessor, Henry C. Schroeder of Nevada City, is developing the English Mountain quartz mine under lease. A strong shoot was recently found, samples returning $10 to $40 per ton in gold. James Holdsworth is superintendent.

Grass Valley, October 17.

The Dromedary mine at Grass Valley has been sold by the Berriman family to the Golden Center company for $18,000.

Placer County

At the Herman mine, five miles east of Westville, 20 of the 30 stamps are crushing 100 tons daily; shortage of water prohibits the use of the full mill. Forty men are employed. Winter supplies are going in.

Sierra County

At the Willoughby mine 20 tons of ore yielded $50 per ton; this is a new shoot.——The Keystone near Sierra City is being sampled and examined.——Sinking is under way at the Bald Mountain Extension gravel claims.

Trinity County

In the news pages of the Press last November was mentioned the case of J. Hoyle jumping the well-known Bullychoop mine, and re-locating the claims. A company is to be formed to further develop and extract ore from the property, which is well equipped.

Tuolumne County

Acting for Eastern capital, F. W. Page, manager of the Royal Consolidated mine at Hodson, Calaveras county, has taken a bond on the Republican property near the Eagle-Shawmut mine near Sonora for $65,000, on certain terms. The main shaft is 700 ft. deep; good ore is open between 500 and 650 ft. A 20-stamp mill is part of the equipment.

COLORADO

Clear Creek County

At the Capital mine the upper adit being driven to cut the Aetna vein is in 1000 ft., with 234 ft. to go. The advance in September was 120 ft., working one shift and hand drilling.

Work is to be resumed at the Gambetta zinc mine on Republican mountain.

Gilpin County

Machinery for the American Metals Producing Co.'s plant has arrived at Black Hawk, where it will be installed at the old Rocky Mountain mill.——The Senator company sent ore to the Iron City mill last week.——Good progress is being made in overhauling the 10-stamp mill at Mountain City.

Lake County (Leadville)

It is probable that the Yak mill in California gulch may resume work early in 1916; it has been idle for six years. Originally it was erected by the American Zinc Extraction Co., and bought later by the Sutton Steel & Machinery Co. of Denver. The ruling of the State Tax Commission will have an effect on the mill being started. It is assessed at $58,505, which is claimed to be too high.

Progress at the Anderson and St. Louis adits is good.

Teller County (Cripple Creek)

The Vindicator company paid its third quarter's dividend of 3%, equal to $45,000, on October 25. The total for this year is $180,000, and $3,217,500 to date. Net earnings for the quarter were $225,000, from which five notes were paid for the purchase of the Golden Cycle mine. This makes 19 paid. Development on No. 18 of the Golden Cycle has disclosed two different oreshoots, according to the president, A. J. Zang, making double the length of the orebody on No. 17 level, but of lower grade. Work on No. 16 and 17 levels has opened additional ore, and one drift on No. 17 has gone a good distance into Vindicator ground, and it will connect with No. 19 level of the Vindicator. Shaft-sinking is well under way. At 1600 ft. in the Vindicator work on the south extension of the north orebody has resulted in a large quantity of good ore being opened. Interesting developments are expected.

Lessees at the C. O. D. mine have shipped some rich ore from a shoot at 600 ft.——Lessees at the Abe Lincoln are producing from 75 to 100 tons of ore per week. Encouraging prospects are reported from the 800-ft. level.——Lessees at the Deerhorn are extracting ore from a depth of 80 to 100 feet.

Probably the Neville mill, on the Free Coinage property, Bull hill, will resume soon. The Zenobia dump is to be treated. Lessees at the Granite property on Battle mountain have cut from 8 to 18 in. of $34 ore.——The Dillon mine nearby shipped 500 tons of ore in 16 days.

According to an official note, the Golden Cycle mill at Colorado Springs would treat 43,500 tons of ore in October, a record.

So far the Ella W. mine has produced 17 cars of ore, and one car per day is the desire of the owners. This is from open-cut work. Others on Tenderfoot hill are active.

The flow of water from the Roosevelt drainage-tunnel is 13,000 gal. per minute.

The recent fine weather has stimulated prospecting in the district, and rich ore has been uncovered at Wanack hill, just outside of the city limits.

IDAHO

Shoshone County (Coeur d'Alene)

Antimony properties in this region are being actively developed and prepared for production, the Coeur d'Alene Antimony Mining Co. being especially busy on Pine Creek. Ore buyers are reported to be bidding keenly for the outputs of the mines.

Bins at the National mine are filled with copper ore, and with a good supply in the mine it is expected that the 500-ton plant will soon commence.

On November 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 218, or $81,750; this makes the total dividends $16,609,500.

It is stated that the Interstate-Callahan company will declare a dividend of $2 per share, equal to $920,000; this will make $1,840,000 since April, and $2,760,000 to date. The output in October was 650 tons of concentrates and crude rich ore.

On November 5 the Caledonia company paid 3c. per share, but as silver is so low the next dividend will be less. The ore is high in silver. Thirty men are employed.

ILLINOIS

Jo Daviess County

(Special Correspondence.)—At Galena, the re-built Joplin separator works is now in operation after several years' idleness, under the control of the Wisconsin Zinc Co. The big producer of this district is the Black-Jack mine formerly the Marsden. Six to 10 cars weekly are recovered here. Federal, North Unity and Great Western mines are steady producers in this camp.

Galena, October 20.

MISSOURI

Jasper County

Owing to the better prices for ores during October it is expected that miners' wages will be increased 25c. per day, while shovelers will get from ½ to 1c. per can extra.

MONTANA

Silverbow County

Approximately 16,000 men are employed in the Butte district. Miners receive $4 per shift at present, so the weekly wage totals $384,000.

The Butte & Zenith mine, six miles from Butte, is likely to be re-opened soon, according to the president, J. Freimuth of Duluth. The property was closed a year ago. The main shaft is 600 ft. deep, and exploration is expected to reveal ore.

At the Butte-Alex Scott mining is under way at 1900 and 2000 ft. depth, while a new level is being opened at 2200 ft. The shaft is to be sunk 200 feet.

The Tuolumne expects to increase its output from 100 to 150 tons per day. Most of the work is at 2000 ft. Stope sets are being placed at 2600 feet.

The Davis-Daly is shipping 7% ore, the output being 100 tons daily. Development at 2500 ft. continues excellent.

The jury's verdict at the enquiry into the North Butte disaster was as follows:

"We find that the cause of death was from shock and internal hemorrhage from injuries received in a giant powder explosion at the Granite Mountain shaft of the North Butte Mining Co. The explosion occurred from some cause unknown."

The powder used, according to S. R. Russell of the du Pont Powder Co., was gelatine-dynamite. The last sent to Butte was made on September 1, 1915, and it was part of this that exploded. Of 12 boxes remaining the product was in excellent condition. The dropping of a stone on a box of dynamite was not considered the cause, as tests of a 2 by 4-in. stone from a height of 75 ft. failed to dent the wood sufficiently to affect the powder.

NEVADA

Elko County

The town of Jarbidge has a population of over 1500 people, and is busy and prosperous. The monthly gold output of the mines is more than $50,000.

Esmeralda County

There are 2800 men employed in the Goldfield district at present, and the town has a population of 4000. The monthly pay-roll is about $300,000.

The final report of the Goldfield Consolidated for September is as follows: ore treated, 32,500 tons; profit, $112,847; net cost, $4.44 per ton, and development, 2204 ft. at $4.60 per foot. Exploration resulted in little of importance. Lessees produced 837 tons of ore with a gross value of $13,109, from which the company received $6908 less the cost of milling and transportation.

Shipments of $40 ore are to be started from the Atlanta 1580 and 1620-ft. levels. The vein at these depths assays $25 to $35 per ton in gold, and 3 to 6% copper.——The Simmerone is also to ship some ore.

At 840 ft. in the Kewanas the ore-shoot has been opened for a length of 160 ft., the north drift for some distance showing 3½ ft. of $40 ore. The ore will be hoisted through the Laguna shaft of the Goldfield Consolidated through which the operations of the Kewanas company are conducted, and where there are good shipping facilities.

At a depth of 1175 ft. in the Merger, the north-east cross-cut is now in quartz in the latite. This work is to explore for the south-east continuation of the rich shoot of the Jumbo Extension.

Six parallel drifts, on different levels, have been opened in the rich shale contact orebody of the Jumbo Extension and all are showing ore of uniformly high grade, extending over a wide area. The most notable of recent developments has been the driving of the 530 drift, about 60 ft. above the 1017-ft. level, and the farthest point to the south-east that has been reached on the contact ore-channel. This drift has been extended over 130 ft., and for this distance has been in ore of high average grade, often assaying over $100 per ton across the full face of the drift.

Nye County

Production of companies and lessees at Tonopah last week totaled 9891 tons worth $203,998.

At 1200 ft. in the Halifax mine rich silver-gold ore has been opened.——A new shoot has been opened at 1350 ft. in the Extension.——The Belmont looks better at present than at any time in the past three months.

White Pine County

The tax-roll of this county is fixed at $13,030,585. The Nevada Consolidated valuation was raised $1,053,111 to $4,724,891; Giroux Consolidated, $82,047 to $183,925.

UTAH

Boxelder County

The Lakeview Mining Co.'s property at Promontory Point

has been optioned to the A. S. & R. Co. for $625,000. High-grade zinc ore is being extracted.

SUMMIT COUNTY

Labor troubles commenced at the Silver King Coalition mine, Park City, on October 26. Insurance, hospital dues, and discharge of certain men are said to be the causes of the dispute. The men are quiet and determined, and have made some concessions. On the 28th the firemen, engineers, and pumpmen 'downed tools,' but the pumps are being worked by several of the men. Prospects of an early settlement are considered good.

WYOMING

It has been found impossible so far to cap the great gas well, which is wasting 250,000,000 cu. ft. per day. The derrick has been destroyed. Engineers of the Montana-Wyoming Oil Co. are constructing a large concrete ring around the well to give a firm anchorage for capping. This well is near Byron.

CANADA

BRITISH COLUMBIA

With one furnace in blast during September, the British Columbia Copper Co.'s net earnings were $7000. The monthly output of copper is 350,000 lb. There are 150 men employed.

Ore from the Lucky Jim mine being treated at the Roseberry mill, near New Denver, is averaging 45% zinc. The output of ore is 100 tons per day.

ONTARIO

If the shareholders agree, the McIntyre company is to acquire control of the Jupiter property at Porcupine. The McIntyre Extension was secured in August, and with the Jupiter the underground work can be better consolidated. The price for the Jupiter control is $152,000. Its ore will be treated in the McIntyre mill, which is being enlarged. The September yield of the McIntyre was $70,268 from 8395 tons of ore, with a profit of $32,723.

During September the Alexo nickel mine produced 583 tons of ore, a decrease.

KOREA

The Oriental Consolidated September bullion production was valued at $131,700.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The Carmen mines, situated in Mexico, just across the Rio Grande from Boquillas, are to be again operated on an extensive scale. The ore is rich in silver and zinc. The property was operated for several years by Germans. It is now owned by F. C. Morehouse and associates. The revolutionary disturbances in Mexico caused the mines to be shut down a few years ago. Ore was transported across the Rio Grande by means of a cable-way; from the landing on the American side it was hauled to Marathon, on the Southern Pacific railroad, 100 miles, in large gasoline trucks. It was found, however, that this method of transport was too expensive, and it is the plan of the owners to place in service 200 wagons between Boquillas and Marathon. Plans are being made for the construction of a line from either Alpine or Marathon to Boquillas, and it is probable that the proposed road will be extended some distance into Mexico.

Boquillas, Texas, October 24.

SONORA

At the end of last week 30 employees arrived at Naco and Douglas from El Tigre. They were not interfered with by Villa.

According to George Kingdon, superintendent of the Greene-Cananea company, conditions at the property are quiet. At the Puertecitos mine, eight miles away, 400 men are working; and 100 at Cananea.

PERSONAL

PHILIP ARGALL is here from Denver.

D. M. RIORDAN has returned hither from New York.

J. POWER HUTCHINS is in the Altai region, Western Siberia.

PIERRE BOUERY, manager of the La Grange mine, is at Boston.

C. W. PURINGTON is due in London on his return from Siberia.

CHARLES T. HUTCHINSON, manager of the PRESS, has returned from the East.

JULIUS RODMAN of Denver is investigating tungsten prospects in Nevada.

L. J. MAYREIS, manager of the Tanalyk copper mine, Russia, is now in London.

GEORGE A. DENNY, until recently in Mexico, has gone to South Africa.

NORMAN C. STINES is in London, on his return from the Ural region, Russia.

SCOTT TURNER has left Tromso and is now in London, on his return to Michigan.

SUMNER S. SMITH has returned from the Matanuska coalfield to Juneau, Alaska.

WALTER BEAM, of Denver, is inspecting mines in the Mother Lode region of California.

JOHN W. FINCH and WILLIAM H. EMMONS are testifying in the Elm Orlu suit at Butte.

F. O. WILLIAMSON of Chicago is making an extensive tour of the western and southern states.

HAROLD B. GLEESON has succeeded GEORGE MACFARLANE as manager of the Mawchi mines, in Burma.

ARTHUR NAHL, manager of the Progreso mine, at Triunfo, Lower California, has returned to Oakland.

THEODORE CHAPIN, of the U. S. Geological Survey, has returned from Ketchikan, Alaska, to Washington, D. C.

STUART A. INGRAM is engaged in erecting a cyanide plant for Messrs. Crowell, Findley & Parsons at Chloride Cliffs, near Rhyolite, Nevada.

OTT. F. HEIZER has resigned the management of the Argo mill, at Idaho Springs, Colorado, where he is reported to have done excellent work.

Schools and Societies

A scholarship endowment estimated to be worth more than $100,000 has just been given to the regents of the UNIVERSITY OF CALIFORNIA, to constitute the Joseph Bonnheim Memorial Fund, for the maintenance of scholarships for young men and women at the institution.

The Joplin, Missouri, branch of the A. I. M. E. met on October 28. There were over 40 members present, including the local and St. Louis men. The sessions included visits to the mines, a dinner, and several papers on geology, mining, milling, leasing, and the activity of the district.

The annual meeting of the California Metal Producers Association was held in San Francisco on October 27. The executive committee re-elected was as follows: ALBERT BURCH, president; G. W. METCALFE, first vice-president; E. C. HUTCHINSON, second vice-president; G. W. STARR, C. E. KNOX, N. CLEAVELAND, and S. W. MUDD. R. I. KERR was elected secretary-treasurer. An increase in membership of nearly 100% since organization is reported, representing approximately 90% of the capital invested in metal mining in the state of California.

THE MARKET PLACE

Weekly summary of metal prices and notes on the markets.

Metal Prices

San Francisco, November 4.

Metal.	Cents per pound.
Antimony	37
Electrolytic copper	19
Pig lead	5.15— 6.10
Quicksilver (per flask)	$97.50
Spelter	16
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	26 —30

Prices for prompt delivery of zinc-dust are as high as 35 cents.

ORE PRICES

Antimony: market irregular, 50 and 60% products, free from deleterious impurities, per unit.....$1.60 and $2

Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....30.00

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 4.—Copper is firm with large enquiries; lead is quiet but firm; zinc is very strong, though moderately active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Oct. 28	49.25	Sept. 22	48.85

The undertone of the silver market remains good, with advancing prices. Little support is coming from India and China. The English and Continental demand for coinage continues fair. Coinage reform is on foot in China, and spread over several years the value of silver absorbed would be worth 266,000,000 Chinese dollars, worth 50c. U. S.

On October 30 a shipment to China amounted to 150,000 oz. The last report of the Tonopah Mining Co. shows silver on hand worth $949,752, nearly 2,000,000 ounces.

Exports during the week ended October 16 totaled 25,359,789 lb., worth $4,860,809. Of this, France took 11,603,698; England, 6,460,009; Russia, 4,625,532; Sweden, 1,568,426; and Italy, 391,419 lb. Imports amounted to 3,893,863 lb., valued at $543,630. Cuba supplied 1,015,980; Chile, 1,000,313; and Japan, 974,275 pounds. September outputs were: Chino, 5,254,286; Nevada Con., 6,021,850; Ray Con., 5,131,466; and Utah Copper, 14,159,289 lb. The last named yielded 15,000,000 in October.

Anaconda is earning $25,000,000, or $10 per share, per year. An increased dividend is expected. All its copper is sold to January 1. Sales in October were 25,000,000 pounds.

On January 1 the Chile Copper Co. will be treating 10,000 tons of ore daily, worth $2.50 per ton at 13c. per lb. for copper. It is suggested that the output be increased to 30,000 tons per day. Reserves are 400,000,000 tons.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Owing to the embargo on the export of lead from Australia, the Chinese market, which has been mostly supplied from there, is in a serious condition. The annual imports to China average about $570,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Date.	Week ending		
Oct. 6	90.00	Oct. 20	92.00
" 13	92.00	" 27	93.00
		Nov. 4	97.50

June	30.72	40.26	Dec.	33.60	....

Tin on November 3 was firm at 36 to 36.50 cents. L. Vogelstein & Co. reports the visible supply at September 30 at 17,286 tons, against 17,094 tons at that time last year.

Eastern Metal Market

New York, October 29.

In the past three or four days the entire market has shown a better tone, and metal prices have advanced without exception. Even consumers concede that copper is likely to go higher. At the present time none is to be had under 18c., and some of the producers are quoting 18.25c. Exports during the month show an improvement. The London price of electrolytic has advanced 10s. over £88. The London quotation for zinc is now £71 10s., and the domestic market is higher also, business having been brisk. Lead has been in heavy demand from Canada and Russia, and this started domestic buyers; as a result of which the New York price has been put at 4.90c., an advance of $3 per ton. The report that Great Britain was planning an export duty on tin has been discredited, and the information started buying of all positions with consequent higher prices. Antimony is tightly held at 35 to 36c., which is not far from the record established in June. Aluminum is extremely scarce, even at its present high price and presents a situation that is troublesome to consumers.

The steel mills are flooded with orders from at home and abroad. The scarcity of open-hearth steel is such that the wider use of Bessemer steel is being urged on many sides. Machine-tool interests continue to combat strikes in the East and in the Middle West. Deliveries are certain to be considerably delayed by the labor troubles.

COPPER

The large producers have great faith in the future of copper. They held to 18c., 30 days, delivered, until today when they went to 18.25c. The metal has been available from secondhands, and some of the smaller producers at 17.75c., cash, New York, making the range of prices 17.75 to 18c. but these prices will be withdrawn. In the early part of this week the market stiffened and 17.87½c. was about the best that could be done; but this was but temporary, and quotations receded to 17.75c., then came a second advance. There is a belief, which is shared by some large consumers, that copper will go still higher than it now is. A good business was done up to October 27, but it was mostly in Lake, inasmuch as this grade commanded no premium over electrolytic. Most of the buying was on the part of war contractors who cover the requirements of every contract as taken. Others refrain from buying far ahead. The domestic consumption continues below par, even the electrical industry not taking anywhere near what it does in normal times. The London price stood for weeks at £88 until today when it advanced 10s. The state of foreign exchange, the pound sterling being quoted on October 26 at $4.61½ and on the 29th at $4.63½, has had a continued bad effect on the market so far as export buying is concerned. Yet exports for the month show improvement, amounting at October 29 to 21,212 tons; but this does not take into account all manufactured products.

ZINC

War munitions' requirements, and a higher market at London, have combined to send zinc quotations upward. Holders were asking, October 28, 14.75c., New York, and 14.50c., St. Louis, for prompt shipment. November was quoted at about 14.50c., December at 14c., and first quarter at 13 to 13.25c. A few weeks ago contracts for the first quarter could be placed easily enough at 10c. Prompt deliveries are active. Some consumers are getting irritated over the irregularity of the market, and, where they can safely do so, are contracting ahead at good prices. A manufacturer of composition bearings, for instance, who does a large business with the builders of machinery, has bought well into next year, and willingly paid a high price on the theory that it was worth something to know that his future supply was secure. The London quotation on October 28 was £70 10s., against £63 10s., on the 22nd. The domestic galvanizing trade continues a poor consumer, though the jobbing trade is showing signs of improvement. Exports have been heavy, totaling 6062 tons up to October 30.

Sheet zinc is unchanged at 16c. f.o.b. smelter, carload lots subject to a discount of 8% for cash.

LEAD

From October 21 to 29 the New York quotations of both the A. S. & R. Co., and independent producers stood at 4.75c., New York, and 4.62½ to 4.76½c., St. Louis, but on the latter date they advanced to 4.90c. New York. The advance was precipitated by heavy buying for export, especially to Russia and Canada. The London market on the 28th was quoted at £24 2s. 6d. The lead market is in a healthy condition, with some of the sellers having nothing to offer for the next two or three months. Exports have been heavy, some having been made by way of New Orleans, where shipping conditions are easier than they are on the Atlantic seaboard. Shipments of the month up to October 30 totaled 3806 tons.

TIN

It was learned this week that the report as to Great Britain contemplating an export duty on tin originated in this country. It probably was given currency for the purpose of influencing the market. English authorities have denied that such a duty had been proposed in London, but say that since the suggestion was made it is likely to be imposed. With the passing of the fear of an export duty a good business was done in all positions of tin, and prices have advanced. The quotation yesterday was 34.75c., spot delivery. With the activity developed a tendency on the part of some operators to gamble by buying on the basis of sterling exchange, their idea, of course, being that the pound sterling will soon advance. The arrivals this month will be insufficient to meet deliveries and stock will be drawn upon. The arrivals up to October 30 amounted to 2000 tons, and there was afloat on that day 4000 tons.

ANTIMONY

Antimony is fast approaching the high record of June, when 38c. was quoted. Chinese and Japanese are quoted at 35 to 36c., duty paid. Canada has been a heavy buyer. The trade believes that the high market will be short-lived, as it is based largely on the shortened supply, and this will soon be corrected. Meanwhile, a sellers' market prevails.

Thomas F. Wettstein, of the United Lead Co., in discussing the effect of the War on the metals, before the recent meeting of the Institute of Metals, said; discussing antimony, that it is perhaps the only metal of the non-ferrous type, of which it can be definitely stated that its present high price is directly attributable to the War.

ALUMINUM

The market continues firm at from 53 to 56c., and all the indications are for higher, rather than lower prices. Consumers of the metals are more puzzled over aluminum than any other metal, for it is difficult to find, even where there is willingness to meet quotations.

The San Francisco Mint reports as follows for September: Australian and Chinese gold bars received, 118,214 oz.; English and Japanese coin, 486,032 oz.; and other gold, 243,748 oz., a total of 847,994 oz., valued at $17,529,585. Silver receipts totaled 52,672 oz., worth $25,083. Coinage executed only amounted to $113,000 and ₱6000. Coin, bullion, on hand at the end of September amounted to $330,635,965.43.

BOOK REVIEWS

Internal Combustion Engines. By Robert L. Streeter. P. 409. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by the Mining and Scientific Press. Price, $4.

The first few chapters of this volume are mainly introductory and contain the usual information regarding the laws of gases, energy, the history of the internal-combustion engine, the Otto cycle, etc. Liquid and gaseous fuels are then discussed. The Otto and Diesel cycles are considered and compared. Considerable space is then devoted to ignition, carburetion, and governing. Power, efficiency, and the cost of power as generated by the different types of engines are then discussed. The different types of both oil and gas engines are described as well as the Humphrey gas-pump. The remainder of the book is devoted principally to engine-design.

Valves and Valve-Gears. Volume II. By Franklin De-Ronde Furman. P. 437. Ill., index. John Wiley & Sons, Inc., New York. For sale by the Mining and Scientific Press. Price, $2.

The first volume of this work, dealing with valves for steam engines and steam turbines, was reviewed in Western Engineering for June 1915. The present volume continues the subject, discussing gasoline, gas, and oil engines. The treatment is the same as in Volume I, and amplification of notes for a college lecture-course, but both volumes will prove valuable to the engineer as well as to the student. The general theory of admission and exhaust for both two and four-cycle engines for different arrangements of cylinders is discussed, together with the various methods of ignition. The application of this theory to the design of valves for ordinary gasoline engines is then considered. A chapter is devoted to the special problems encountered in the design of aeroplane-engines. Valves for gas engines, ordinary oil engines, and diesel engines are considered in turn, and the book closes with a few remarks on the comparative efficiency of the various prime movers.

Purchasing. (Its economic aspects and proper methods). By H. B. Twyford. P. 236. Charts, 112 plates, index. D. Van Nostrand Co., New York, 1915. For sale by the Mining and Scientific Press. Price, $3.

An excellent text book and guide for the instruction of purchasing agents and those whose partial duties include the placing of either large or small orders. Considerable time and money would be saved by both buyer and seller if the principles as outlined by the author were carefully followed by our present day purchasing agents. The splendid example of system as outlined in this book is in itself well worth the consideration of many who are only indirectly connected with actual buying.

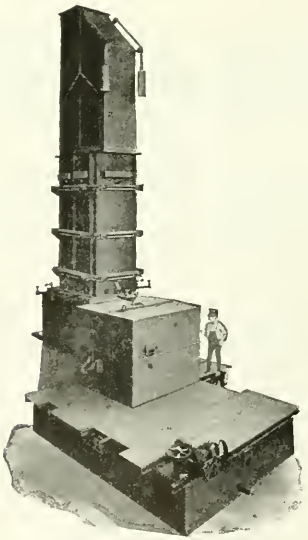
Information based on letters and catalogues from manufacturers.

An Improved Hot-Blast Furnace

This hot-blast furnace is a Partridge type furnace, embodying its original features, with the addition of several improvements. The principal variations from a standard lead or copper blast-furnace lie in the use of a continuous open slot or aperture in place of circular tuyeres at regular intervals, and an arrangement for pre-heating the blast by direct contact with the molten slag.

The furnace consists of a rectangular water-jacketed shaft, a removable crucible resting on a jack-plate, a forehearth enclosed in a chamber connected on one side to the crucible chamber, and on the other to the slag-box, which contains a rotating cast-iron pan. The space between the bottom of the



THE IMPROVED HOT-BLAST FURNACE.

jackets and top of crucible constitutes the tuyere opening. The slag and matte flow continuously into the forebearth, where the matte settles to the bottom and is tapped at regular intervals. The slag overflows onto the rim of the pan which turns slowly beneath, spreads into a thin sheet, and is gradually cooled and solidified by the blast from the blower passing over it. It is granulated and pushed toward the centre by stationary plows attached to beams above, and finally discharged into the pit below, through an automatic device which traps the blast. The furnace is of substantial construction and designed for operation in out of the way places, and far from a base of supplies. It is built entirely of heavy sheet steel and castings, the only brick-work used being the refractory lining for the crucible and settler. The jackets are open at the top to eliminate any danger from explosion, and all joints are welded. Numerous mica peep-holes are provided for the furnace-man to inspect the working of the furnace. This furnace, it is claimed, smelts efficiently and runs 'hot' in sizes prohibitive in standard blast-furnace practice, because of the open tuyere or fusion slot, the hot-blast, and the low-blast pressure.

The advantages of operation claimed for this furnace are numerous and include the following: requires less fuel; produces a higher-grade matte; makes a minimum amount of flue-dust; permits running more silicious slags; produces cleaner slags; admits of intermittent operation; is easily transported and erected; and automatically handles and disposes of slag. The ores suitable for reduction by smelting in this furnace are gold and silver, lead, nickel and cobalt, and tin.

The construction of the furnace, it is claimed, particularly adapts itself to the prime requisite of the process, namely, a voluminous hot blast under low pressure, and when operating as a pyritic furnace, attains its highest degree of efficiency. The most satisfactory fuel is coke, when it can be obtained at reasonable cost. In the semi-arid regions of the south-western part of the United States and Mexico it is generally expensive, in which event charcoal made from scrub timber on the adjoining desert furnishes a good substitute; or small wood blocks dressed with lime to prevent their burning at the top of the shaft can be used. Crude oil has not been proved a practical blast-furnace fuel so far. The furnaces are built in sizes ranging from 5 to 100 tons' daily capacity. The furnace is manufactured by the International Smelting & Manufacturing Co., 2151 Lawrence street, Denver, Colorado, from whom full details will be furnished upon application.

A Large Electric Locomotive

Butte, Montana, people are accustomed to seeing large electric locomotives hauling long ore-trains, etc., but the arrival last week of a giant engine for the Chicago, Milwaukee & St. Paul railroad attracted considerable interest. It will operate between Three Forks and Deer Lodge. A trial run was made over the Butte, Anaconda & Pacific line, which is already electrified, the other to be ready at the end of the year. The General Electric Co., which has constructed the locomotive, has contracts for other engines, sub-stations, and line material, and with the Montana Power Co. for the construction of transmission of 133 miles of main line between Three Forks and Deer Lodge. This is the first step toward the electrification of four engine divisions extending from Harlowton, Montana, to Avery, Idaho, a distance of about 440 miles, with approximately 650 miles of track, including yards and sidings. Plans are being made to extend the electric line from Harlowton to the coast, a distance of 850 miles, should the operating results prove as satisfactory as anticipated.

A comparison of six months' steam and electric operation has shown a saving of 20% on the investment or cost of electrification; the tonnage per train increased also. The locomotive is the first to be designed for railroad work with direct current motors using 3000 volts. Some details are as follows:

Total weight, tons	284
Motors	8
Length of locomotive, feet	112
Horse-power rating, continuous, each motor	375
Horse-power rating, one hour, complete locomotive	3440
Horse-power rating, continuous, complete locomotive	3000
Trailing load capacity, 2%, tons	1250
Trailing load capacity, 1%, tons	2500

EDITORIAL

T. A. RICKARD, Editor

RUMORS OF PEACE negotiations indicate the growing financial perplexities of the belligerents.

TRADE continues to expand all over the country, the revival being accentuated by seasonal business. The West is beginning to feel the effect.

THAT $500,000,000 Anglo-French loan has been swallowed without any signs of financial dyspepsia. The world has 'money to burn' these days.

ANACONDA produced 24,900,000 pounds of copper in October. This happens to be exactly equal to the output of the Lake Superior mines during the same period.

SOME of the profits from war business ought to be diverted to the improvement and equipment of the railways, of which one-sixth, as measured in mileage, is in the hands of receivers.

DURING the three months ending September 30, the immigrants arriving in the United States numbered 85,606, as against 90,813 emigrating from the country. Thus the net loss was 5207.

IN FOUR DAYS bombardment along a 20-mile front in Champagne the French used 4,500,000 shells. That means the consumption of at least 9000 tons of copper 15,000 tons of lead, and 4000 tons of zinc.

TRANSACTIONS on the New York Stock Exchange during the month of October represented a total of 26,639,000 shares, these being the biggest dealings in any month since March 1907. As compared with October 1913, the increase last month was 7,000,000 shares.

SERVIA produces about 7000 tons of copper per annum, chiefly from the Bor mine, which is controlled by a French syndicate. This source of copper may prove useful to the Germans, although the Servians, of course, will have dismantled the mine before retreating.

LONG CREDITS are essential to business with the South American countries. There has been much talk of utilizing the opening afforded by German and British pre-occupation, but, as yet, the one notable effort to win trade in South America has been the campaign of the National City Bank of New York.

IN our issue of June 26 we mentioned the intention of the U. S. Steel Corporation to build a zinc plant at Donora. The first zinc has now been drawn, just 103 days after ground was broken for the erection of the plant. Thus work requiring usually a whole year was done in 15 weeks. The output is expected to be at full capacity, namely, 40,000 tons, by January next.

FROM BUTTE we have received an interesting letter commenting on the litigation now in progress there. It will be found under the heading of 'Special Correspondence.' By the way, the Judge in the Elm Orlu case was at one time a hoisting-engineer in this very mine. No wonder that he decided to see some of the geologic evidence underground for himself, in view of conflicting expert testimony. He also tried the Minerals Separation *v.* Butte & Superior flotation case.

WE learn, through our Mr. Charles T. Hutchinson, who has just returned from a visit to the Eastern centres of business, that the leading manufacturers of mining machinery have not diverted their energies to the making of munitions as much as is generally supposed. They are having their share of war orders, but the bulk of their output continues to be along established lines. Orders for mining and metallurgical machinery and supplies are being received to an extent not equalled since the collapse of the Nevada boom in 1907. Representative companies are working at full capacity, and even employing extra shifts to cope with new business. Their chief difficulty is to get prompt delivery of raw materials, such as brass and steel sheets. The War is benefiting them indirectly; the demand for metals in the making of munitions is stimulating the production of copper, zinc, lead, antimony, quicksilver, and a dozen minor mineral substances; this, in turn, creates a demand for the machinery and other equipment required by the miner in his operations; thus our friends the manufacturers are being kept profitably busy. It is time that this tide of prosperity flowed over and around our comrades in the mining profession; indeed, such prosperity would have been manifest before now if the disorders in Mexico had not stranded a large number of capable engineers. But there should be work for all ere long.

ELECTROLYTIC precipitation of metals from cyanide solution is a subject on which Mr. G. H. Clevenger, now Professor of Metallurgy in Stanford University, is peculiarly competent to write. We publish a lengthy abstract of an important paper by him on this subject. It is well known that the late Professor Christy of the University of California did a lot of experimental work in this direction, but it was inconclusive. Even now, after experience in various parts of

the world, as recorded by Mr. Clevenger, it cannot be said that electrolytic precipitation is likely to gain in favor. It is too costly both in equipment and operation. At the present moment some interesting trials are being made in the use of sodium, in the form of amalgam, as a precipitant for gold and silver. Experiments are being conducted at the Homestake and also in several Tonopah mills, on the initiative of Roessler & Hasslacher, the New York manufacturers of cyanide and other chemicals. Precipitation with sodium is rapid—1¼ minutes as against 70 minutes with zinc shaving—but the amount of mercury to be handled makes it expensive to install or to use, now that the price of mercury is so high. Of course, the regeneration of the cyanide is a decided advantage, as in the precipitation with aluminum. We hope to publish details at an early date. Reverting to Mr. Clevenger's paper, it will be noted that he is severely critical of precipitation with zinc-shaving; by a happy coincidence we have received a timely article on this phase of the subject by Mr. Jay A. Carpenter, of Tonopah. This will be published in an early issue.

IN the October bulletin of the Canadian Mining Institute we find a discussion, by Mr. Alfred Stansfield, of a proposal made by Mr. D. H. Browne "that all smelting plants should co-operate to establish a bureau of unpublished metallurgical research." Apparently the idea is that the various smelting companies would contribute odds and ends of information, of no particular value to themselves, as Mr. Stansfield indicates, in the hope of finding among the other rejects a hint of something useful to them. In order to make such information more generally available, Mr. Browne suggests that some engineering society, like the Canadian Mining Institute, should act as custodian, with arrangements for sending a type-written copy of any part of the records to any person particularly interested. Whereupon Mr. Stansfield comes forward with the suggestion of selecting specialists to investigate the experimental records for a moderate fee. All of which indicates a praiseworthy effort to save useful experience and to pass it to those whom it may help. We agree that a big amount of experimental work is squandered for lack of information concerning similar work previously done. If every metallurgist would record briefly the negative results of his research there would be much time, labor, and expense saved from year to year. At the present moment there are tests being made, in the flotation of complex sulphides and the leaching of copper ores, for example, that traverse ground already pioneered, but concerning which nothing has been published. Secrecy, due partly to modesty, partly to meanness, is a bar to progress, but, thank Heaven! there is less of it than there used to be. The big men in the profession are generous givers of information to their fellows. Secretiveness works both ways; so does expansiveness. The best way of getting information is to begin by giving it. After all, 97½% of what any of us know came to us without payment. The least we can do is to try—vainly, of course—to square the debt.

The Great Problem

We take pleasure in publishing a letter from Mr. F. H. Newell, now head of the Civil Engineering department of the University of Illinois. He writes in response to our invitation, for in a preceding issue we had asked him to tell the readers of this periodical what were the purpose and aim of the American Association of Engineers, recently organized at Chicago, with himself as the chief sponsor. We thank him for his explanation, which will be read with keen interest; but we are frank to say that it is a little disappointing as a demonstration of the need for another engineering society. In fact, we have no reason to believe that the "great problem," namely, that of causing the community at large to appreciate the engineer and his work, will be solved by the creation of another association to include all branches of engineering. We had thought that the Panama Canal had demonstrated what the engineer can do, that the tunnels under the Hudson had suggested something of the kind, that every system of electric light and water supply hinted at the engineer somewhere in the background, that every steamship and every railroad told the same story, even to the least observant. If something more is to be done to emphasize a basic fact, it might be better to found local societies, like the Engineering Society of Cleveland, so as to establish the position of the engineer in his home community, rather than attempt by the aid of another grandiose scheme to impress the nation.

While not holding a brief for any existing society, we are surprised to find the older organizations charged with neglecting to fulfill their proper functions. We question whether one of those functions is to act as an employment agency. Of such, there are many. Some scheme of insurance against unemployment might be undertaken—by an insurance company. That could only be done, like the employment agency, on a business basis and on distinctly commercial lines, something quite apart from a professional society. However, we like the spirit of Mr. Newell and his friends. They want to do something for their fellows. In the last paragraph of his letter, Mr. Newell suggests the bringing together of the younger men, with a view to a common inspiration, excluding "the relatively cold and unsympathetic body of men who have been notable in engineering work." Surely he does a grave injustice to a large number of his fellow engineers, even to his contemporaries. On the contrary, we believe that steps should be taken to bring the old and the young, the experienced and the inexperienced, into closer touch. If our engineering societies devoted less time to the reading of dry papers and the desultory discussion of arid technology; if they devoted their periodic assemblings to the discussion of the very topics mentioned by Mr. Newell, namely, the engineer's place in the social organism, his duty in the community, his work in the world; and if this were accompanied by round-table talks between the veterans and the juniors, then something useful might be done. Let the young men tell their seniors some of those ideals of conduct

that become dimmed in the dust of daily life, and, in exchange, let the older fellows transmit their experience so that the younger may start life at a better advantage. To obtain experience without the sacrifice of ideals, that is the "great problem."

Applied Geology

The efforts of the geologist to guide the footsteps of the miner in his underground search for ore have usually come, like individual experience in life, too late to be used profitably. Belated post-mortems on particular mines are common enough, but they are rarely applicable to other mines, so that to the engineer a great deal of interesting investigation seems too academic in character to be of practical use. Yet each correlation of cause and effect is of immense value; every time the local distribution of ore can be proved to have been modified by definite structural relations, or enrichment can be traced to the agency of definite chemical reactions, we move a step toward the realization of the economic geologist's aim, namely, the ability to state where ore is likely to be found. Usually, however, the scientific enquiry begins when the mine is worked out or in trouble. Our readers will remember how the Waihi mine, in New Zealand, came to grief suddenly in 1910. This property was rated a short time previously as one of the great gold mines of the world, for it had produced $52,317,000 worth of gold and distributed $22,201,940 in dividends. It was owned by an English company of 500,000 shares. These shares fell from $50 to $17.50 in the course of 12 months, marking a depreciation of 16½ million dollars, none of which has been recovered. The system of veins that had yielded plenty of rich ore down to about 1000 feet below the surface suddenly became poor. To explain this unfortunate development, first, there came a report from Mr. R. E. Williams, who is no geologist, but a capable superintendent. He imputed the impoverishment to a change of rock, to "a soft decomposed country-rock, similar to that found near the surface." This was a reference to the soft weathered rhyolite, which, in the Waihi district, overlies the flows of andesite constituting the prevailing country-rock. In the adjacent mine, called the Grand Junction, the Waihi veins do not begin to be productive until below 500 feet, for at that horizon the veins penetrate the andesite. However, the report of Mr. Williams was not adequate to the occasion, so Mr. G. A. Richard, at that time manager of the famous Mount Morgan mine, was engaged to make an investigation. He also was more distinguished as a good manager than a specialist in economic geology, but any lack of experience in such matters was obscured by a liberal use of scientific terms, for his conclusion was that the impoverishment might be due to "a zone occurring between hydro-genetic and pneumato-genetic ore." Even this did not comfort the shareholders. That was in February 1911. Meanwhile the New Zealand Geological Survey had been preparing a bulletin on the geology of the Waihi goldfield. The examination had been commenced by Messrs. J. Mackintosh Bell and Colin Fraser in August 1910, and the staff of the Waihi mine had obtained an inkling of their conclusions long before the bulletin itself was issued in May 1912. In that publication Messrs. Bell and Fraser give it as their opinion that "a fairly large boss of dacite of rather irregular shape has intruded an earlier-formed complex of rudely bedded dacitic lava-flows." It was suggested that the veins are productive only in this intrusive dacite. That, if true, would be a geologic inference of immediate practical value. If the geologist cannot tell the miner where he is likely to find ore, it is something to the good if the geologist can tell him where he is certain to find none. In such case it would become a question of confining search to the dacite, which, unfortunately, is constricted in depth, without any compensating concentration of richness in the veins. Since the official report was made, we have heard nothing more concerning the Waihi, which, as a gold mine, continues to decline in importance; but its neighbor, the Grand Junction, is being developed with a courage not abashed by scientific dicta concerning the deeper penetration of the veins into an uncongenial terrain. The geologic discussion, moreover, is not closed. Mr. Arthur Jarman has been making a careful examination of the local geology, as illustrated in the Grand Junction workings, and is able now to come forward with a flat rebuttal of the Bell-Fraser hypothesis. In a paper just published by the Institution of Mining and Metallurgy, Mr. Jarman, who is assistant-manager of the mine in question and formerly was professor of mining engineering in University College, Auckland, gives ample evidence to show that the supposed intrusive dacite is "identical and continuous with" the bedded dacite. He disproves the massive character of the former by finding carbonaceous partings and flow-structure in the very heart of the supposed boss of dacite; in short, he concludes that ore "may reasonably be expected to continue beyond the limits of the supposed intrusion." For that relief the miner at Waihi will give him much thanks. No definite reason for abandoning exploratory work along the veins has been established. But we may conclude that certain of the dacitic flows afford a specially favorable wall-rock; therefore the delineation and tracing of these flows will be the next task of the geologist. Such association of richness in a vein with the character of the wall-rock is not uncommon. For instance, we may quote the mines in the andesitic breccia of the San Juan region, in Colorado, where good stopes coincide with those parts of the vein that penetrate a particular layer, or succession of layers, of breccia, usually finer-grained than the rest. Where, at Waihi, such favorable beds are traced on their dip, there will be a favorable chance of finding ore even in ground deeper than any existing workings, for as yet the mining operations in this district have only penetrated a thousand feet, so that they have not yet reached a stage that can be called 'deep,' as compared with other productive localities. Moreover, oxidation extends to 800 feet below the surface and the ground is full of water on the bottom levels. It remains to follow the clue given

by Mr. Jarman, to whom not only the Grand Junction company, but all the operators in that part of New Zealand, are under pleasant obligations for a practical hint likely to facilitate the search for ore.

Sampling on A Big Scale

In this issue we publish a description, by Mr. Downie D. Muir, Jr., of the method adopted in the sampling of the Ebner mine, near Juneau, Alaska. This is interesting as illustrating the practice evolved for the ascertainment of the gold contents of the enormous masses of low-grade ore found in the big lode now famous by reason of the large-scale operations of the Gastineau and Juneau mines, both of which owe their existence to the pioneer work done in the old Perseverance mine by Messrs. Arthur L. Pearse and J. R. Mitchell. In order to take samples intelligently it is necessary to have some idea both of the structure of the lode itself and of the distribution of its metal contents. The lode-channel in question consists of a broad band of black slate, steeply inclined, bordered by diabase on the hanging-wall side and by schist on the foot-wall. The slate is traversed by numerous small and irregular veins of quartz impregnated with metallic sulphides, chiefly pyrite and galena, associated with particles of native gold, both fine and coarse. The lode, therefore, belongs to the 'stringer-lead' type, resembling that of the Treadwell mine. In both cases dikes of diorite intrude into the lode-channel and appear to modify the distribution of the gold. On the whole, therefore, the structure is complicated, if not confused, in detail, although the net result is to offer a big width of quartz-veined rock sufficiently rich in gold to become the object of profitable mining operations. Obviously, that part of the lode is 'ore' which contains enough gold to be mined and milled at a profit; like all sagacious mining the operations become selective; the paramount question is to ascertain what portions of the mass are to be extracted and what portions are to be left in place. Ordinary sampling, with a moil and a hammer, making a cut across the width of ore, is impracticable because the mineralized rock to be tested may be several hundred feet wide and may extend for several thousand feet in length. Beyond the bigness of the dimensions there is the greater difficulty presented by the uneven size of the gold particles, which vary from the microscopic to aggregates large enough to vitiate any ordinary sample. In this respect the Gastineau-Juneau-Ebner lode differs from the Treadwell, in which all the gold is fine. Further, we may add that while 90% of the Juneau gold is 'free-milling,' or easily amalgamable, only 50% of the gold in the Treadwell lode is thus amenable. Since the average of the ore runs from $1.50 to $2, it is plain that an error of only 25 cents per ton, equivalent to one part in 2,333,280 parts by weight of ore, becomes serious. Finally, while the particles of gold vary in size, they also vary in their distance apart, to such an extent as to impair the doctrine of averages on which all sampling at regular intervals is based. Thus the experienced engineer does not delay in concluding that ordinary sampling is hopeless as a means of arriving at an estimate of the yield to be obtained in the course of regular milling operations on a scale of over a million tons per annum.

Speaking generally, the lower the grade of an ore the larger the sample required to ascertain its contents. Concurrently, the less regular the distribution of the metal-contents the larger and more numerous the samples should be. In a broad way, the sampling should reproduce, as nearly as possible, the conditions under which the ore will be mined. Hence it has become customary to supplement the sampling of large bodies of low-grade ore by actual milling or concentrating in a trial plant capable of treating lots of ore broken in the mine under the conditions approximating those of future operations. Small stamp-mills have been built or leased for such a purpose; at Juneau trial-runs on the usual diminutive scale have been deemed inappropriate to the immensity of the work in hand. The Gastineau and the Juneau companies used old mills ranging in size from 30 to 100 stamps in their systematic sampling of the big lode. In both cases, of course, the equipment included the proportionate concentrating plant. In sampling the Ebner mine, a 5-stamp battery was used, supplemented by an amalgamating-barrel, a settling-pan, and a Wilfley table. No effort was made to elaborate the metallurgical treatment, the main point was to crush bulk ore and to find out first how much gold it contained and then what proportion of that gold was readily amalgamable. The description shows that great care was taken to obtain accurate samples at various stages of the milling, employing automatic devices and checks of various kinds, all of which are explained in detail by Mr. Muir. In developing the mine for the purpose of a thorough examination, the ground was sampled at intervals in the ordinary way wherever the indications were favorable; when a cross-cut passed into ore, a bulk-sample for the mill was obtained by making a cut 3½ feet deep and removing a slab of that thickness the full height of the cross-cut for a length of 12 feet; this sample was broken and removed before the next one was taken. The work of testing, of course, was aided by the knowledge of the lode previously obtained in the neighboring mines. Indeed, the most reliable sample yet taken was the 500,000 tons of ore mined and milled from the Perseverance by Mr. Mitchell. Since then the Alaska-Gastineau, mining to a bigger width, has undertaken to exploit lower-grade ore on a much bigger scale, at a lower cost and a smaller profit, in proportion. It yet remains to be determined what is the economic limit, having regard not only to the operating cost but the factor of time, as applied to the redemption of capital. In enterprises of this character it is necessary to spend millions of money in order to extract millions in gold; there comes a time when the cost of money is a fatal addition to the cost of mining; both must be included in arriving at the final profit, which is the difference between the total value of the gold produced and the total cost of winning it from the ground.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Flotation in Australia

The Editor:

Sir—With regard to Mr. Edward H. Shackell's letter in your issue of the 23rd inst., taking exception to my statements in connecting with the history of the De Bavay process, as reported in my article, published in your paper of July 17, I may state that the account of Mr. de Bavay's invention given in the article was to the best of my memory as related by him to me.

The final success of the plant by the installation of cone-separators was generally understoood due to the manager of the company, Mr. Gepp. Certainly this method was tried and discarded by Mr. de Bavay while I was with the company. However, if my description was in error, I certainly regret it, as I had no other intention than to give a correct account.

Referring to the personal part of Mr. Shackel's letter, I may point out that there are generally two sides to these matters, and my own experience was no exception. Though manager of the company I was not permitted to manage, and intimated emphatically to the Chairman of Directors that continuance of such arrangement was not agreeable to me. My resignation—as per copy attached—followed.

C. S. Galbraith.

Keddie, California, October 25.

American Association of Engineers

The Editor:

Sir—In your editorial you kindly suggest that I tell your readers what is the "great problem" that is to be solved, and you ask, "Is it co-operation with a view to fraternal benefits, that is, insurance against ill health or lack of work?" In part it is, but in a larger part the great problem is that of dispelling ignorance and of diffusing information among the thinking people, and especially the taxpayers, as to what the engineer can do and is doing for the benefit of mankind. If there existed a full appreciation of this matter, there would be little said as to the necessity of an organization for insurance or any other purpose. In other words, the great obstacle to progress by the engineer in improving the welfare of mankind, and incidentally his own, lies in the slowness with which correct information is diffused among the people who will most be benefited.

Growing out of this lack of knowledge arises the condition that today a considerable portion of the engineering profession is unemployed or its services are not being utilized in the most effective manner. The great problem as it relates to employment would not be a problem if there were full appreciation of the fact that every day these men are out of employment there is a direct loss not so much to them as to the entire community. A result of this lack of employment is, for example, the delay or lack of construction of sanitary systems, causing uncounted and unnecessary deaths or days lost in sickness. One of the ramifications of the great question is how to diffuse information to the public, how to tell the facts to the man who pays the bill in a way that he and the public can and will assimilate the facts and make them part of their consciousness.

It is true that we have a large and increasing number of high-grade technical publications, but these are read mainly by the men who are already well informed on fundamentals. The great body of citizens does not see nor know of these publications nor grasp the significance of the developments that may be made. The engineering societies are publishing tons of literature, all of which, however, is addressed to the members and is not within the range of the ordinary reader. Little, if any, effort is being made to build up systematically a broad knowledge of what is being accomplished. In comparison with efforts being made in other directions, the engineering profession as a whole cannot view with pride the lack of modern up-to-date or scientific effort to diffuse information among the great mass of the people who are directly or indirectly benefited by engineering works.

As a specific example of what may be done, I may cite the case of the Engineering Society of Cleveland, Ohio. Only a few years ago it was practically a moribund organization. A few enthusiastic men determined to try to make it take its proper place in public esteem. They worked hard and learned many things of value to themselves and to others. Without discussing their struggles, it may be said today that the citizens of Cleveland know and respect this society as a force for good in the community. It has done more to elevate the whole engineering body in popular esteem than any other one effort made in recent years. Success was obtained largely through taking the public into its confidence. With the helpful aid and advice of certain of the local editors the society succeeded in giving out to the public of Cleveland—in short readable statements—a few elementary facts as to what the engineer does and can do for the community. The public responds quickly to such information when given in the proper spirit and obviously without desire for personal advertising.

What has been done at Cleveland can and should be

done in every centre of population. It is, however, doubly difficult to do this in many localities because of the fact that the existing engineering organizations are under the control of men once young and aggressive but now tending to ultra-conservative habits of thought. They do not see that times have changed and that there are new matters continually arising. They have clearly in mind the saying: "Old men for counsel," but they often forget that counsel without action has little value or perhaps are unwilling to observe the rest of the proverb: "Young men for action."

It is to be regretted that it is sometimes necessary to organize new associations to do the work which might better be done by existing bodies. These new associations may accomplish their purpose by stirring up the older societies and bringing them to a larger appreciation of new needs.

In reply to your question "What is the new association going to do for the profession?" the reply may be given, that this particular association hopes to do those things which the older organizations "passed by on the other side" namely, diffuse information to the reading public, and bring together the younger men of the engineering profession who do not see any reason why they should join the older societies. It hopes to establish for the profession a broad, thoroughly honest method of seeking employment, one which may be developed from a scientific study of the whole subject. It is trying to bring together the coming men, the men who have yet to make their reputations, and who will find through association with their fellows an inspiration which is lacking in the relatively cold and unsympathetic body of men who have been notable in engineering work. Whether it succeeds or not, it will at least have made its contribution toward a better fellowship and a better understanding of the problems which surround the life of the young struggling engineer.

F. H. Newell.

Urbana, Ill., October 15.

The Editor:

Sir—Relative to Mr. Newell's championship of the body of engineers in the country, there is no doubt that the American public fails to appreciate engineers. They are not appointed on public boards and committees even in cases where engineering advice is sadly needed; instead, lawyers, politicians, and 'reformers' are selected to do things of which they know nothing and never will. From the smallest village council to the Federal government, there is a lack of proportionate representation of engineers in public appointments and advisory boards. More to the point perhaps is the incomplete appreciation of engineers by business firms and corporations. Commercial bodies fail to comprehend the immense possibilities of the employment of technical men, and do not see that engineering graduates can be broadened into efficient officials of unlimited grasp. The amazing growth of Germany's industries during the last 25 years was in large measure the result of appreciation and utilization of technically trained workers. Instead of considering engineers as men apart from ordinary use and behoof, industrial organizations should cultivate, encourage, and, if necessary, educate technical graduates along lines mutually beneficial to both sides. Unlimited possibilities exist in this direction, and the sooner American businessmen realize it the better for them—and the engineers.

There is a possibility, perhaps, that the engineer tends to resist being drawn out; he is inclined to be narrow, aloof, superior, and cynical, scorning self-advertisement and publicity, for the reason that public life and commercial routine present unlovely aspects to him, full of inconsistencies that he does not understand. He prefers to have things come to him rather than seek recognition in a public way, although he will work untiringly at a problem when once started and encouraged. Yet to a considerable degree this detachment of the engineer is "all a sort of shell," he knows, and we know, that he is one of the most sympathetic and human of men at heart.

If Mr. Newell can arouse the engineers to commingle with the public, and the public to consider the engineer as not only a machine—but also a citizen—the result will be mutually beneficial and of signal importance to the entire country. However, some doubt may exist as to whether a gigantic association would achieve this desirable result. Big associations and scattered organizations are bound to involve a lot of misplaced enthusiasm and a stupendous array of misunderstandings; withal they are extraordinarily difficult to administer satisfactorily. The engineer is primarily an individualist, and is liable to distrust huge organizations of his fellows; he recognizes that a lot of nonsense, injustice, and superficiality are bound to be present.

Undoubtedly there is need for a man of Mr. Newell's standing to start a campaign of justice for the engineer. If nothing else results, the advertising and educational effect on the general public, by calling attention to an important profession, hitherto unappreciated in anything like its due proportion will be salutary and welcome. Certainly, too, it is the young struggling engineer who should be assisted by engineering societies—the older successful men do not require help.

Mine Accidents

The Editor:

Sir—In reference to your article in the issue of October 9 regarding mine accidents and their causes, I would like to state that my own experience indicates that 99 out of every 100 times the management is to blame. As to a miner coming down a ladder with powder, caps, and fuse in addition to his candle, have you ever tried it yourself? also what provision has the management made for carrying these things? As for the caps reposing on the box of powder, was there any place provided for the caps out of harm's way, except to lay them on the floor where anyone might come and knock, kick, or otherwise disturb them? Now, I believe that if managers were to go into the workings as a miner under the same condi-

tions as the actual miner, they would soon find what makes irresponsible laborers and miners, and why supposedly unnecessary risks are taken. At one time I had charge of some work under a chief of good repute, which in most respects he deserved, but he would not spend the money necessary to make the handling of powder convenient or safe. There was no satisfactory method of thawing it, and no one to look after caring for it properly. I kept at him to build a small place for thawing powder within a reasonable distance, which in this country is not closer than 150 ft. of the mouth of any tunnel. At last permission was given and the place built, but do you suppose he would put any kind of heating appliance in it? Nothing doing; the same old method: thaw it the easiest and quickest way possible regardless of accidents. Now I don't say that all managers are like this, but I will say that being chief engineer or manager is a different thing from being a miner. In most cases a miner could not manage a property; but how many engineers can actually do the mining? Can they recognize a good hammer-man, or can they take hold of tools and do the work? If they cannot, then it is hard for them to see where and why the miner is careless. Again, under such conditions a man who carries his powder on his person to keep it thawed and takes all kinds of chances, does more work, and gets ahead better than the man that will not do these things. What is the outcome? The careful man gets fired, the management showing the other miners that the same will happen to them if they don't do ditto. Now this is not the condition under all managements, but when a good management gets miners that have had a schooling of the other class, the accident risk is the same.

Gas Engines and Altitude

The Editor:

Sir—'Concentrates' in the issue of October 23 says, "Altitude is not a factor of gas or gasoline engine," etc. This is wrong. Altitude is an important factor in an internal-combustion engine. The capacity of any internal-combustion cylinder is in direct proportion to the amount of oxygen that can be taken into the cylinder. The fuel is but secondary, being enough to combine properly with the oxygen. The higher the altitude, the less the weight of oxygen per cubic foot of air, and the lower the possible horse-power that can be developed in any particular engine. In bids submitted to me for some large Diesel multi-cylinder engines, they were rated at 2250 b.-hp. at sea-level, and at 1900 b.-hp. at Miami, Arizona, the approximate altitude being 3700 ft. It has been proposed that at high altitudes the intake air for big Diesel motors be compressed by Root blowers, or that the cylinders of the motors be increased in diameter.

J. Parke Channing.

Miami, Arizona, October 25.

[Mr. D. W. Brunton writes as follows: "The 'Concentrate' is strictly correct, but I am afraid it might convey the impression to a careless reader that a gas or gasoline engine would develop the same power at high altitude as at low, which is not the case. The density of the charge in a cylinder at the end of the intake stroke cannot be greater than the atmospheric density outside; consequently, although the gasoline engine works equally well at high or low altitudes, as you state, it does not receive as heavy a charge at high altitudes as at low, and therefore the power developed is correspondingly less."

A. T. Kasley, chief engineer of the S. & G. E. department of the Westinghouse Machine Co., East Pittsburg, says: "We have found by experience that this is not true [that altitude is not a factor of gas or gasoline engine operation.—Editor.] The engine depends upon the expansive force of a mixture of air and gas or gasoline, and if the air is rare, due to altitude, it seriously affects the possible power that can be obtained from an engine. At an altitude of 6000 ft., an engine will only develop a little over two-thirds as much power as it will at sea-level."

In *The Gas Engine*, H. H. Clark writes as follows: "For two years I have been running a Foos gas-engine at 10,000-ft. elevation in Mono county, California. The engine is used for hoisting gold ore from a 200-ft. shaft, raising a 700-lb. bucket in 67 seconds; it is a 7-hp. engine, and has worked so satisfactorily that I purchased a smaller one to pump water at Calipatria, Imperial county, at a point 198 ft. below sea-level. I see no difference in the working of the two engines, except that I have to give the higher one all the air possible, which I did by taking out the air-pipe entirely and drilling the hole larger."—Editor.]

Woven Wire for Revetment

The Editor:

Sir—In your issue of July 10, 1915, in the article entitled 'A Novel Debris Dam,' the statement is made that this application of woven wire for a revetment was being made for the first time. This is a mistake, as the author and designer can see by reference to the files in the Patent Office, Washington, D. C. of 1906, for I patented such application at that time and have used it in a great many different forms since.

Some years ago I used it in the construction of a dam near Roswell, in New Mexico, in connection with irrigation work; in 1905 and 1906 in Park county, Colorado, in hydraulic mining as a revetment to protect wasteways; in 1914 in Nigeria, Africa, on dam construction and to protect road-ways across drifts against wash-outs.

It is in use in Spain, near Leon, on a tributary of the river Sill, as a protection against erosion of banks and to protect bridge-piers.

Persons wanting to use this can make arrangements with H. G. Peake, of the Union Construction Co., 604 Mission St., San Francisco.

Bodaibo, Siberia, September 1.

Sinking the Woodbury Shaft, Michigan

By J. M. BROAN

[In rock-drilling, shaft-sinking, and blasting practice, the Lake Superior copper and iron regions are taking the lead. The following description of sinking a large vertical shaft written by a mining engineer at the Newport mine (often mentioned as the largest underground iron mine in Michigan) is interesting for the following points:

1. Two 'headers' were used in the shaft for distributing compressed air to the drills, each header being able to supply 7 plugger-drills and a blow-pipe. A header is a convenient device for conducting compressed air from the air-main to the rock-drills which are hung on the header when not in use; the whole outfit can be lowered and raised with speed and ease.

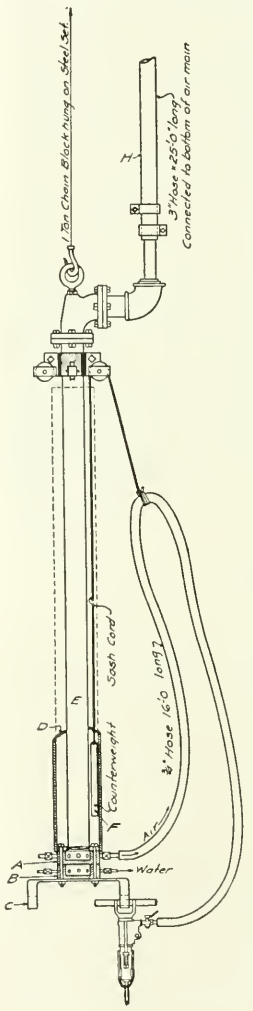
2. Jack-hammer drills, 12 in number, with $\frac{7}{8}$-in. hollow hexagon steel up to 10 ft. long (an unusual length in sinking) were employed. The bit on the starters was $2\frac{1}{4}$ in., while all other bits were reduced by $\frac{1}{8}$-in. diameter for successive lengths. For granite, Carr bits gave satisfaction, but mechanical drill-pullers had to be contrived for freeing stuck drills.

3. In blasting, two or three sticks of 100% blasting gelatine were placed in the bottom of the hole, then 80% strength for the remainder, except a single cartridge of 60% for containing the detonator. An average of $26\frac{1}{2}$ lb. of explosives was consumed per foot of shaft.

4. The shaft was 'timbered' with steel sets.—Editor.]

*The Woodbury shaft, being sunk by the Newport Mining Co. at Ironwood, Michigan, is situated 100 ft. from the contact between the iron-bearing formation and the underlying strata. The shaft is vertical, with its length at right angles to the strike of the formation. The over-all dimensions are 13 ft. 1 in. by 21 ft. 1 in., having six compartments, which will accommodate 2 skips, 2 cages, 1 ladder-way, and piping. The first 100 ft. of sinking was in quartzite; from 100 to 715 ft. in depth there were alternate gray and red slates and quartzite, below which is granite. The temporary head-frame is 60 ft. high, with the trestle so arranged that it is possible to hoist rock in any of the compartments and dispose of it by means of a haulage-motor and car to a common stockpile. During the sinking of the first 700 ft., the hoisting was done in three compartments by means of a single-drum hoist, operated by a 50-hp. motor and a double-drum hoist, operated by a 70-hp. motor. While sinking this portion of the shaft, a duplex horizontal steam-hoist was being installed by the Allis-Chalmers Co. for handling the cages and by July this was used to operate a bucket in the fourth compartment.

Three belt-driven compressors, of the Ingersoll-Rand Imperial type No. 10, each driven by a 50-hp. motor, furnish air at 90 to 100-lb. pressure to 12 jack-hammer drills. The air-line is a 6-in. wrought-iron pipe for permanent use. The equipment is in some respects different from ordinary practice. Two 'headers' are used for distributing air to the drills, each of which will accommodate 7 jack-hammers and 1 blow-pipe. When not in use the 'headers' are hung to one side in the head-frame and can be easily lowered by means of a sling beneath the bucket; while in use they hang on a small chain-block fastened to the bottom shaft-set. When ready to drill, all that is necessary is to remove the jack-hammer from the hook and pull downward, the counter-weight keeping the slack hose out of the way while drilling. One of these headers can be taken from its position on surface and placed on the chain-block below ready for drilling in less than five minutes, only one connection being necessary. In the softer slate, water-tube pistons were used in the drills and air blown through in place of water. Later, when drilling in the granite, the drilling speed was not as great and it was found that sufficient air could be supplied through the ordinary piston to clear the choppings from the drill. The steel, which is $\frac{7}{8}$-in. diameter, hollow hexagon, is made into lengths varying by 1-ft. changes from 12 in. to 10 ft., with a $\frac{1}{8}$-in. difference in gauge for each drill; the first bit being $2\frac{1}{4}$-inch.



HEADER, SHOWING DRILL HUNG ON LOWER PART.

Until the granite was reached, the four-point or cross-

*Abstract of paper read before the Lake Superior Mining Institute in 1915.

bit was used, but the wear on the gauge became such as to warrant a change. It was then that the Carr bit was tried. In the stratified rocks many difficulties were caused by fitchered holes and stuck drills. Rather than abandon a hole, much time was spent in freeing a drill, so that necessity led to the devising of two mechanical drill-pullers. In case only a short portion of the steel emerged, a long goose-neck was used, while if two or more feet of the drill remained out of the hole, a shorter puller could be applied. In either case an inverted jack-hammer drill supplied the power necessary to extract the drill. In the soft slate, 10-ft. drills were used with little difficulty and cuts measuring 9 ft. were blasted successfully. In the slate about 470 ft. of drilling per cut was required, which could be completed in four or five hours. In the quartzite, dike, and granite the gauge on the steel would not hold up long enough to permit the use of any drill over 8 ft. long.

In these hard rocks about 425 ft. of drilling is necessary, which can be done in seven or eight hours. When the shaft was started, Du Pont crescent, double tape, and triple tape fuses were tried and it was found that while the double and triple tape fuses were more impervious to water, they were too brittle when exposed to air and water, and unless handled with great care would break the powder-train. Crescent fuse, however, was found to be sufficiently waterproof for use here, as it is seldom that a fuse is exposed to water for more than 15 minutes before ignition. Crescent fuse is more pliable and can stand abuse. All exploders were made with fuse of the same length, which, when the holes had been charged, were cut so as to fire them in the order desired. The ends of the fuse were then placed in a paste-board box containing a small amount of black powder. An electric fusee ignited this powder, which, in turn, lighted all the fuse simultaneously. For convenience and saving of fuse, several boxes were employed, thus requiring shorter fuse than if a single box was placed in the centre of the shaft. In each cut, 450 ft. of fuse and ½-lb. of black powder were used. This gave off such a large quantity of fume that as depth was attained Du Pont electric blasting-caps and electric delay-fuse igniters were introduced; these required less care in handling and gave satisfactory results. To regulate the time of exploding of a detonator, all that is necessary is to make the fuse of different lengths. The maximum length manufactured is 12 in., of which ¾ inch is inside the casing, leaving 11¼ in. to be divided among the different delays desired. In several preliminary tests it was found that a ¾-in. delay was a minimum that would give positive results; if cut shorter than this the holes are apt to explode out of order on account of inaccuracies in cutting and also on account of the 10% variation in the burning speed of all fuse. On the other end of the fuse a No. 8 cap is crimped. The joints where the fuse enter the brass casing on one end and the cap on the other, are both bound with friction-tape, the former having been dipped in melted roofing-cement and the latter greased, to insure a positive resistance to water. The detonator is placed in a cartridge of 60% nitro-glycerine dynamite and the shell tied with a string securing the joint which is also well greased.

Since the steel used is only ⅞-in. diam., the bottom of a deep hole is very small and cannot contain sufficient explosive to break the burden in a satisfactory manner. To offset this disadvantage without drilling more holes, two or three sticks of 100% blasting gelatine is placed in the bottom of each hole. The remainder of the charge, with the exception of the cartridge containing the detonator, is 80% blasting gelatine. Experiments by the Du Pont Co. have shown that 60% nitro-glycerine gives a maximum efficiency for speeding the action of a charge, and for this reason a single cartridge of this strength is used to contain the detonator. It is placed as near the

DRILL-PULLERS.

top of the charge as is considered safe from being cut off by the breaking of an adjacent hole. Cartridges of sand are used for tamping. An average of 26½ lb. of explosive per foot of shaft has been used in the first 800 ft., or about 1 pound for every 13 cu. ft. of excavation.

In preparing a blast, the leads of No. 20 copper wire are laid over the centre of the portion to be blasted and the various igniters connected in parallel with them. The reason for this method of connection is to prevent a misfire in case of a single defective igniter or connection, which would cause the failure of the blast if connected in series. It is safe to figure about one ampere per path. From 30 to 35 holes is about the maximum number fired at any one time. The switch for closing the circuit is locked in a small cupboard on surface, and the key is kept by the shift-boss during the preparation of the blast. Every igniter is tested with a small galvanometer before being used. After a blast the smoke is cleared by a draft forced through a 12-in. pipe by a 7-hp. fan on surface. At first the fan was used to draw the smoke out, but by reversing the current, less time was required to clear the smoke.

During the first 700 ft. of sinking the broken rock was hoisted in three buckets, each of a capacity of 26 cu. ft.

To render the shoveling as easy as possible, steel plates were used as sollars, with considerable success. The steel sets are made of 6-in. H-sections and are hung on studdles of 3 by 5-in. angle-iron. Sets are spaced at 6-ft. centres in the slate, and 8-ft. centres in the granite. At every 100 ft. of shaft a bearing-set is placed under the set. These are supported temporarily by large spruce sprags about 12 or 15-in. diam., which will be replaced later by concrete. While in the slate the steel sets could be kept within 15 ft. of the bottom without being damaged, but in the granite if hung closer than 30 ft., blasting is liable to harm them. Guides are made of 6 by 7-in. pine, dressed, and are framed to span two 8-ft. or three 6-ft. sets. Laths for lining the shaft are made of 2-in. hardwood. These also serve as forms for concreting when sinking operations are completed. The ladders are made of $\frac{3}{8}$ by 2-in. strap-iron sides and $\frac{3}{4}$-in. iron rungs. They are long enough to reach over two 8-ft. or three 6-ft. sets, and in both cases have about 4 ft. projecting above the sollars. The sollars are made of 3-in. plank.

All lighting is by electricity. A single lamp is placed under each ladder-sollar; at the bottom of the shaft, two clusters of four lights each are hung, one below the staging to give light to the miners and one above to give light to the construction crew. An electric signal-system is used, the wires being run down the east side of the shaft beneath the ladders. By means of a jumper connected to a common return-wire, either signal-bell can be run from any sollar. The men employed in the shaft are as follows: One shaft-captain, 3 shift-bosses, 36 miners, 11 construction men, 1 electrician, 4 landers, 2 motor-men, 4 hoist-engineers, a total of 62 men. The sinking was started on March 1, 1915, and at the time of writing (July 27) is 901 ft. in depth. The maximum footage per month was 201 and the minimum 173 ft. To guard against accidents from falling fragments, hard hats, made of felt treated with resin and shellac, are furnished to the men, and no one is allowed to enter the shaft without one.

Bolivia has an area of 708,195 square miles, which is over twice the area of the Pacific Coast states of California, Oregon, and Washington; the population is 2,267,925, while La Paz, the capital, has but 82,000. With no coast and being a rough country for railroad construction, Bolivia remains to a large extent undeveloped, though its mineral wealth is undoubted. Previous to the War, its principal foreign connections were with England, Germany, France, and Belgium. In the first five months of 1915, the export of ores and metals aggregated 20,894 metric tons, compared with 19,059 metric tons during the same period in 1914 previous to the War. They were: tin, 17,055 tons; copper, 2037; bismuth, 211; wolfram, 243; antimony, 1315; silver ores, 33 tons.

Boring for oil on the island of Madagascar off the African coast is proceeding at depth. This island, a French colony, is larger in area than either France or Germany.

Mineral Output of the Philippines

The Division of Mines, Bureau of Science, at Manila, has issued its report on the mineral resources of the Territory in 1914, a review being compiled by Wallace E. Pratt. Good progress was made in gold mining. After considerable discussion, the new royalty of 1.5% on the gross output of gold, became effective on January 1, 1915. As much as 5% was proposed by the Legislature, to cover precious and semi-precious metals. Although some copper development was done, capital did not become interested to any extent. The Tellus Syndicate, of Frankfort, Germany, examined the old Santa Barbara mine at Mancayan. Reserves were estimated at 225,870 tons of 5.22%, and 150,000 tons of 1.75% copper ore. Iron-smelting in Bulacan continued normal. Coal mining remained inactive. No drilling was done in the Bondoc Peninsula oil area.

The mineral output was as follows:

Product.	1913.		1914.	
Metallic:	Quantity.	Value.	Quantity.	Value.
Iron, metric tons ...	227	₱64,471	199	₱56,274
*Silver, fine ounces ..	.....	.....	10,000	9,878
Gold, fine ounces....	42,011	1,736,724	52,235	2,349,267
Total value of metallic...		₱1,801,195		₱2,415,419
Non-metallic:				
†Clay products		₱460,000	.....	₱465,000
†Lime	11,050	102,700	11,000	100,000
‡Sand and gravel....	689,011	595,645	723,461	625,429
‡Stone	197,039	350,041	206,890	367,543
†Salt, metric tons....	19,500	575,000	20,000	590,000
Mineral waters, litres.	270,000	60,000	293,381	50,000
Total value non-metallic..		₱2,143,386		₱2,197,972
Grand total		₱3,944,581		₱4,613,391

*The gold bullion produced carries from 5 to 30% of silver as a natural alloy.

†The manufacture of this product is a household industry in a large part of the Territory; statistics are, therefore, not available, and estimates are approximate.

‡Production of the Bureau of Public Works, which is the largest single producer, estimated for 1914.

A little more than 50% of the Philippine production of gold came from quartz mining at Aroroy, Masbate, where the Colorado, Syndicate, and Keystone mines are the principal producers. The P. A. Schwab property at Aroroy also produced some gold, and other prospects have been actively developed.

Dredging is responsible for nearly 44% of the 1914 output. The principal producers among the dredging companies are all in the Paracale-Mambulao district, in Camarines province, and include the Gumaos Placer Company.

Peru has an area of 680,000 square miles, which is over four times that of the state of California, and a population of 4,500,000, while Lima, the capital, has 150,000. The national debt of the country is stated to be $6.50 per capita of population. The deposits of copper, lead, silver, oil, vanadium, and rare metals are important.

THE ELMER MINE, ALASKA.

Sampling Low-Grade Ore on a Large Scale

By DOWNIE D. MUIR, Jr.

Introductory. The ore in the Ebner mine, near Juneau, Alaska, consists of two classes; first a tough fine-grained diorite or meta-gabbro, brown in color and containing a network of quartz stringers or veinlets; second a black carbonaceous slate similar to the diorite as regards distribution of quartz. Practically the entire value of the ore is in free gold; the sulphides are less than 1% and are very low-grade. Distribution of the free gold in the ore is uneven, the content increasing with the number of quartz stringers or the amount of quartz. The gold varies in size from the finest particles to small pieces weighing a sixth of a milligram, a considerable portion also is found in flakes the size of a pinhead.

Experience in the district indicated that the best method of determining the average value of this low-grade ore was by crushing representative lots in a small stamp-mill. Since the ore averages only $2 per ton, it is obvious that an error in sampling of 25 cents represents from 25 to 33% of the margin of profit. In conjunction with development work the rock was sampled regularly until ore was encountered in the cross-cuts. A continuous cut 3½ ft. deep, the height of the cross-cut, was broken from one side; for convenience the length of sampling was limited to 12 ft. This was sent to the mill prior to breaking the next cut. By using care in the alignment of the drill-holes the cut amounted to 2½ tons per foot. The assays of these separate 12-ft. sections were then combined to secure the average over any particular section.

The mill erected at the start contained a battery of five 850-lb. stamps and the flow-sheet was simple. The ore from the mine passed over track-scales and a 1½-in. grizzly, the oversize went to a gyratory crusher and joined the undersize in the ore-bins, where the moisture-samples were taken. The battery-screen had 40-mesh diagonal slots 0.5 in. long and 0.025 in. wide. The pulp from the battery passed over silver-plated amalgamating plates into amalgam-traps and thence into the tailing-launder. The checks adopted in the sample-mill did not

differ materially from those used in ordinary practice of milling free-gold ores, namely, that the gold in the tailing plus the recovery from the plates shall approximately equal the assay of the splash from the battery. Samples of the battery-splash were taken at regular intervals by hand just below the lip of the mortar, and the tailing samples by an automatic sampler, the mill operating on a 24-hour cycle.

At the outset satisfactory checks were not obtained; naturally, a discrepancy that might have been acceptable with a $15 ore was prohibitive in this case. Several factors entered into this discrepancy such as absorption of gold on new plates, impracticability of removing all the accumulated amalgam at the completion of each test, scouring action of the pulp when the ore dropped in grade, and the tendency of the slime to form a scum on the plates, preventing amalgamation. The controlling factor, however, proved to be the type of battery-screen used. The length of the diagonal slot allowed many flakes of gold to pass, rendering intermittent hand-sampling useless, as well as preventing mixing and rolling of the sample from producing a homogeneous sample from which representative assay-pulps could be cut. Numerous screen-tests confirmed this inference when it was found that with a product which had not been ground to pass 40-mesh woven-wire screens, it was impossible to cut separate assay-pulps that would check each other.

Sand Method. To prevent such error, a 40-mesh woven-wire screen was adopted with an automatic sampler for the battery-splash, eliminating the amalgamating-plates entirely. This method, termed the 'sand method,' for purposes of differentiation, is shown on the left side of the flow-sheet.

The automatic sampler, actuated by a hydraulic cylinder under a constant head, was installed just below the battery, the pulp from which was caught in a V-shaped box the same length as the mortar and 4 inches wide. A 3-in. pipe 4 in. long was set flush, at the apex of the V, with the inside of the box, and in a vertical position, discharging the pulp from the battery into a 12-in. launder 2 ft. long, set on a slope of an inch per foot. The proportions of the launder, together with the slope and spiral action of the discharge from the 3 in. pipe, resulted in an even flow of pulp over the entire width of the launder. The cutter of the automatic sampler working immediately below the lip of this launder took a sample amounting to from 1 to 1.75% of the battery-feed. As the stamp-duty was 0.09 ton per hour the resulting sample weighed from 150 to 250 lb. per run of 22 hours. The remainder of the battery-discharge that passed the sampler was at first run over amalgamating plates to save such gold as would amalgamate without any great amount of attention. The amalgam recovered on the plates, however, did not enter into the sampling of the ore in any way, and they were later removed to make way for a Wilfley table used in the concentrate method.

The following screen-tests on the battery-splash show the fineness to which the ore was crushed prior to any quartering for assay-pulp.

Mesh.	Percentage of weight.	Percentage of average value in product.
On 40	....	....
" 50	23.34	33.21
" 80	7.36	16.04
" 100	7.36	13.08
" 120	4.92	8.14
" 150	2.46	4.49
" 200	0.61	1.24
Through 200	49.65	19.49
Lost in screening	4.30	4.29
Total	100.00	99.98

Note: The percentage of weight lost in screening is assumed to have the average value of the sample.

The battery-splash sample was dried thoroughly in a drier constructed for that purpose, in which it was possible to start the drying of the wet pulp at a low heat, gradually raising the temperature as the excess of moisture was evaporated, at which time all danger of loss of a portion of the sample through boiling and bubbling had passed. When dried the sample was weighed, placed on steel plates, coned and quartered to approximate 50-lb. lots, then rolled on a rubber sheet and cut to final assay-pulps of 3 to 5 lb. each by means of a Jones sampler, and subsequently ground to pass 150-mesh for assay. In the case of screening the final cut for assay through the 150-mesh screen the men in the grinding-room were provided with large sheets of white glazed paper on which all material remaining on the screen was dumped. This paper with its contents was then scorified; in the event of metallics being found, their value was proportioned to the weight of pulp from which they had been derived and this was added to the assay of the pulp. The result was accepted as the average assay of the battery-splash; it marked the completion of the first stage of the method.

The reject from the battery-splash sample was charged with about 40% by weight of water into a 3½ by 2-ft. amalgamating-barrel filled to nearly the centre line with flint pebbles. The barrel was revolved at from 50 to 60 r.p.m. for 18 hr. at the expiration of which time an excess of mercury was added, an ounce of mercury to 10 lb. of dry pulp giving the best results. The pulp was allowed two hours of additional grinding in contact with the mercury before being discharged by means of a steel launder into a 3-ft. settling-pan. Longer grinding with more mercury resulted in excessive flouring, which rendered difficult the subsequent panning for its recovery, thus tending to decrease rather than increase the recovery by amalgamation.

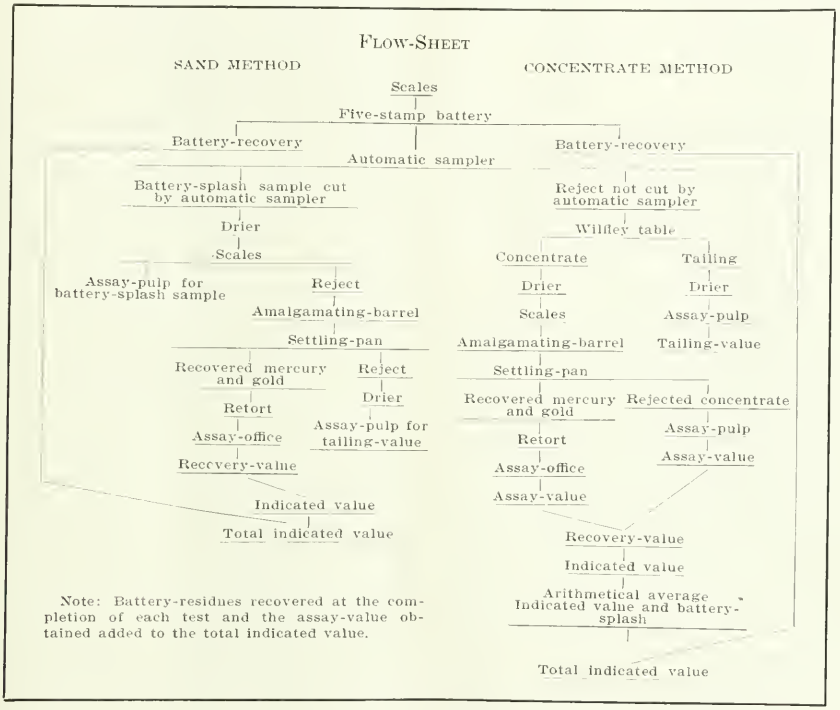
For this kind of inside amalgamation, where the barrel must be entirely discharged and cleaned once every day (or after each sample), it is best to use a barrel having a readily removable head. Small blow-holes, which the usual casting is apt to contain, are exposed from time to time in the inner surface of the barrel as the grinding proceeds and, acting as an amalgam trap, fill with hard

amalgam. The inability to inspect inside of the barrel satisfactorily through the usual small hand-hole may cause one or more of these amalgam-filled cavities to be overlooked, with a resulting salting of the following sample, and reduction in value of the sample under treatment. The effectiveness of a salting, however small it may be, is obvious when it is considered that the value of the gold recovered from a 150-lb. sample in this manner is multiplied approximately 13 times to indicate the gold that would be recovered from a ton of such ore.

The fineness to which the sample was reduced after 20 hours of treatment in the barrel is shown by the following screen-test:

Mesh.		Percentage of weight.	Mesh.		Percentage of weight.
On	80.....	0.8	On	200.....	3.55
"	120.....	7.1	Through	200.....	88.30
"	150.....	0.0			
			Total	.....	99.75

Following the treatment in the barrel, the pulp was agitated in the settling-pan for two hours by means of a mechanical agitator, having four paddles, one fixed at each quadrant of the circle to a spindle that was revolved by gears underneath the pan. A screw adjustment permitted the raising or lowering of the paddles to any desired height above the bottom of the pan. The height of 1½ inches at 15 r.p.m. proved satisfactory for settling the mercury. At the end of this period the pulp was allowed to settle sufficiently long to siphon off a reasonable amount of the supernatant liquid. The thick pulp was drawn off to within two inches of the bottom through the side-discharge openings in the pan. The pulp remaining in the pan, containing practically all of the mercury and amalgamated gold, was then drawn off through the bottom-discharge into another tub and panned many times, recovering as much of the mercury and amalgamated gold as possible. The loss in mercury amounted to from 2½ to 5% of that originally fed to the barrel and was due to the 'flouring' and 'sickening' in the barrel. No attempt was made to eliminate this fouling through the introduction of reducing agents in the barrel or acid treatment of the mercury during the panning operations, as any small amount of gold that this mercury may have contained was accounted for in the assay of the tailing, as will be seen from the subsequent treatment of the reject from the settling-pan and panning operations.



The mercury recovered, weighing from 15 to 25 ounces, according to the weight of the sample treated, was then retorted. This proved to be a slow and tedious operation, as the large excess of mercury carrying a relatively small amount of gold made necessary a slow treatment to insure collecting of the gold in a button at the bottom of the retort. Rapid treatment under these conditions resulted in scattering the gold and leaving thin scales firmly attached to those portions of the retort from which the heat had flaked the chalk lining.

After retorting, the contents of the retort, including gold, chalk, and any foreign material such as sulphides

mixed with the mercury, were sent to the assay-office. The gold thus obtained, in proportion to the weight of the pulp from which it was recovered, represented the yield per ton. This gave the 'recovery-value' and marked the completion of the second stage of the method.

The reject from the panning of the lower two inches of pulp from the settling-pan, containing the major portion of the 2½ to 5% of mercury loss, was added to the remainder of the reject from the settling-pan. The combined pulp was dried and quartered in the same manner as the battery-splash sample to a final 3 to 5-lb. pulp for assay, the result being the 'tailing value,' marking the completion of the third stage of the method, which was also the final stage so far as this one sample was concerned.

In drying, this pulp was subjected to a heat of from 150 to 300° F. for a period of 15 to 20 hours. Although this heat was relatively low, it was apparently sufficient, considering the length of time in the drier, to volatilize the floured mercury, as no traces of this were found on the 150-mesh screen when preparing the final pulp for assay. Thus any gold that this mercury may have contained was accounted for in the tailing-assay.

Numerous quartering tests on the pulp from the barrel, after the removal of 75 to 80% of the free gold by amalgamation and from 2½ to 15% by failure to pass the battery-screen, proved conclusively that various assay-pulps cut from the entire sample would check consistently to within 2 or 3 cents per ton. Further assay-pulps, cut from a composite sample of the entire daily tailing-rejects for any one test covering a period of several days and weighing 500 to 1000 lb., checked within an average of 3.5 cents per ton (disregarding the plus or minus sign) the average calculated value of the separate tailing-samples covering the same test. By this method, after the rough points were ironed out, the tailing-value plus the recovery-value checked the battery-splash sample within 8 cents for a run of 200 tons. Later, when working smoothly, this discrepancy was reduced 4.8 cents for runs of the same tonnage.

On completion of the mill-sampling of any one section of desired width in the mine, the residue in the battery was removed and the free gold extracted by aid of an ordinary rocker. This gold was then melted, the fineness and value determined, to be apportioned to the tonnage from which it was derived. As might be expected when using such fine battery-screens, this value exceeded 10% of the total.

The battery recovery when added to the combined daily tailing-value plus combined daily recovery-value for any one test was considered as the total indicated value of the ore, provided the sum of these two checked the combined daily battery-splash sample covering the same test.

In this method it will be noticed that the recovery-value and tailing-value are based on the treatment of a very small proportion of the total tonnage milled or sampled, and, as previously stated, any error in the recovery-value is increased to a damaging extent in the final result. The fact that the recovery-value plus tailing-value checks the battery-splash cannot be accepted as proof positive that the correct value of the ore has been ascertained, unless it is conceded that the automatic sampler cuts a true and average sample from the battery-splash. In this case such was proved to be the case by subsequent work.

Concentrate Method. To prove the accuracy of the average cut by the automatic sampler we adopted the concentrate method in which the determining of the recovery-value and the tailing-value was based on the treatment of the entire tonnage milled and was run in conjunction with the sand method.

A No. 6 Wilfley table was installed on the lower floor of the mill to take the entire battery-discharge with the exception of that portion cut out by the automatic sampler as a battery-splash sample. The resulting concentrate was then dried, weighed, and the ratio of concentration determined. This was followed by charging the concentrate from the 22-hour run into an amalgamating barrel considerably larger than that used in the sand method, employing iron balls rather than flint pebbles. The quantity of water added to the charge varied; it had to be sufficient to render the resulting pulp liquid enough to permit thorough permeation by the mercury. The treatment of concentrate in the barrel was similar to the sand treatment with the exception of the amount of mercury and the time of contact, both of which were increased on account of the higher gold-content of the concentrate per unit of weight over the crude ore. An ounce of mercury was fed for every 2½ lb. of dry concentrate and the time of contact lengthened to 3 hours.

The reason for not cutting out a head-sample from the concentrate at this point prior to amalgamation, thus saving the time and expense incurred in amalgamation, is somewhat analogous to experience when endeavoring to secure an accurate battery-splash sample with the 40-mesh slotted screens. The concentrate contained (exclusive of the gold retained in the battery through failure to pass the battery-screen) the bulk of the free gold in the ore and was a high-grade product, considering the ratio of concentration as compared with the crude ore. This fact and also the fact that from 80 to 90% of the value of the concentrate was amenable to amalgamation indicates that a slightly greater proportion of the value was in free gold, because rusty gold in small quantity was not uncommon.

Following amalgamation in the barrel, the concentrate was discharged into a settler, the thin amalgam being recovered as in the sand method. The loss in mercury in this case varied from 8 to 29% of that originally fed, the increase in loss over the sand method being due to the larger quantities handled and the slight oxidization of the concentrate while drying, this tending to 'sicken' varying quantities of mercury.

The concentrate-reject after having been deprived of its free gold was quartered in the usual manner to a final 3 to 5 lb. pulp for assay. The assay-result when divided by the ratio of concentration and added to the value of the retort-gold treated in the same manner was considered the recovery-value per ton. The figure ob-

tained in this manner corresponded closely with the recovery-value in the sand method, differing only in the fact that it was based on the treatment of the total tonnage milled and it represented, in addition to the gold amenable to amalgamation, the major portion of the relatively small proportion of gold chemically combined in the concentrate.

Tailing from the Wilfley table was sampled by an automatic machine actuated by water flowing alternately into either compartment of a V-shaped box divided at the centre, at which point the box was supported by a single bearing. The tipping action of the box at alternate ends resulted in swinging a rigidly affixed pendulum to which the sample-cutter was attached across the discharge of the launder. Plungers attached to the bottom of the box at each end, working in water-filled cylinders with sufficient clearance to permit free movement, resulted in giving the cutter a uniform rate of speed across the launder. The rate at which this cutter worked was made to conform as closely as possible with the cutter that sampled the battery-splash, so that samples of approximately equal weight were obtained.

The sample of the Wilfley-table tailing was then dried and quartered to a final 3 to 5-lb. pulp as previously described. As in the sand method the sum of the tailing-value and recovery-value was checked against the battery-splash and the arithmetical average of the two accepted as the 'indicated value' of the ore exclusive of the battery-recovery which was determined at the conclusion of the test and taken into account in the total indicated value of the ore.

The checks obtained by this method, as well as those by the sand method and a fair comparison of the accuracy of the two methods, may be seen in the following tabulation. This shows the discrepancy between the battery-splash and the sum of the recovery-value and tailing-value on the same ore when run in conjunction. Each test represents the combined results of three or four daily samples or the run of an equal number of days, and does not take into consideration the battery recovery; that being the same in either method.

Test number.	Tons milled.	Sand-method discrepancy between B.-S. and R.-V., T.-V.	Concentrate-method discrepancy between B.-S. and R.-V., T.-V.
16	35.791	$0.039	$0.063
17	42.915	0.108	0.034
18	31.511	0.044	0.021
19	32.284	0.055	0.059
20	33.083	0.019	0.008
Total	175.584		
Average discrepancy		$0.054	$0.037
Arithmetical average of discrepancies using both methods			$0.0405

The tests on the above 175.5 tons of ore represented the sampling of approximately 70 ft. of continuous width of orebody.

There is little to choose between the two methods, each having its distinct advantages. The sand method is the more rapid and less expensive, but it is open to the objection that results are based on the treatment of so small a proportion of the total tonnage milled and therefore is absolutely dependent for accuracy on the perfect working of the automatic sampler at the battery-splash. The results in the concentrate method, on the other hand are based on the treatment of the entire tonnage milled and in the long run would probably prove the more accurate.

When run in conjunction, as in this case, these methods are considered to act as balance-wheels for each other and to establish a sure and safe control of the value of the ore to within 4 or 5 cents per ton. The success of the method lies primarily in fine grinding prior to any attempt at sampling and also in careful and painstaking effort throughout each step, as well as a tendency at no time to rush the work to a point where the accuracy of the results can be impaired. This effort was also extended to the assay-office where it is sufficient to state that all the work amounted virtually to umpire assaying, 3 to 6 charges of 1½ to 2 assay-tons being run on all mill-samples.

Copper in China

According to a Consular Report there are some rich copper areas in the Yunnan province. The late Ch'ing dynasty depended on the metal from that province for the minting of copper 'cash.' The Imperial government appointed officials to supervise the mining works, and at one time the Yunnan mines regularly shipped 6,000,000 catties (1 catty = 1⅓ lb.) of copper to Pekin every year. The best mines are situated in the Tungchuan district. During the Taiping rebellion mining operations were suspended, the supply of copper to Pekin was cut off, and the Government had to resort to minting 10-cash copper pieces so as to save material. After the Taiping rebellion, not much success has been obtained in operating the properties.

On the establishment of the Republican government the copper mines were taken over by the Tungchuan Mining Co. This company had a capital of $300,000, the Government supplying one-half of the capital. But the capital has never been fully subscribed, and the company has never secured satisfactory results in development of the mines. Consequently the output is small, and as the adoption of antiquated native methods means greater expenses, the price quoted by the company for its copper is high. Thus the various Government mints found it unprofitable to purchase Yunnan copper, and therefore the raw material for the minting of copper coins was all secured from Japan and other countries.

The Government recently organized the Gold Mining Bureau, under the Ministry of Finance, to control the gold, silver, copper, and other metals necessary for the minting of coins. The department now requests that a high official be appointed to superintend the development of the copper mines at Tungchuan. The Tungchuan Mining Co. will be taken over by the Government, so that better results may be secured.

Electrolytic Precipitation of Gold, Silver, and Copper From Cyanide Solutions

By G. H. CLEVENGER

Introduction

*The present unsettled condition of the metal market, more particularly as regards zinc and aluminum, which are used now almost exclusively as precipitants in the cyanide process, makes a consideration of electrolytic precipitation, which is apparently the most feasible substitute, of particular interest at this time.

The solutions precipitated in present-day cyanide practice may contain a great variety of compounds arising from the decomposition of the cyanide, as well as from its combination with elements in the ore treated, or introduced by chemical methods of precipitation. The principal constituent of such solutions, if zinc precipitation were not used, would be simple alkaline cyanides, alkaline hydrate, gold and silver, and copper, if it occurs in a soluble form in the ore undergoing treatment. The proportion of these various constituents present, particularly of the gold and silver, is extremely small compared with the amounts of metal present in solutions made by extraction processes in other industries.

Perhaps a clearer idea of the small amount of metal involved, particularly in the case of gold, will be obtained by expressing the proportion fractionally. In solutions containing 0.50 oz. of gold per ton, an unusually high proportion, the gold would form only 1/58,332 part of the solution. In a solution containing 0.05 oz. gold per ton the gold would constitute only a 1/583,320 part. In the case of waste solutions, which should be precipitated before they are discarded, it is not unusual to deal with solutions containing less than 0.01 oz. of gold per ton (20 cents), or only 1/2,916,600 of the total weight of the solution. Tail solutions containing only 1 or 2 cents per ton are common at many mills using zinc-dust precipitation.

The electrolytic precipitation of gold and silver from cyanide solutions, therefore, involves the total precipitation of an extremely small weight of metal from solutions containing a comparatively small proportion of soluble salts, and which are therefore poor electrical conductors. The fact that the alkaline cyanides are readily decomposed by electrolysis and that the economy of the cyanide process depends upon the continued re-use of the solvent make it imperative to precipitate with the minimum decomposition of cyanide, and preferably with a regeneration of cyanide.

Siemens-Halske Process. The precipitation of gold and silver from cyanide solutions by electrolysis, employing a soluble anode of the metal to be deposited, had been practised in electroplating long before the complete precipitation of gold and silver from the dilute solutions resulting from ore treatment was attempted by electrolysis, using an insoluble anode. In 1887 Dr. Siemens, acting upon observations made at his plating plant at Berlin, Germany, taken together with the statements of chemical authorities that gold was soluble in solutions of the alkaline cyanides, developed a process of gold and silver extraction involving the use of dilute solutions, and electrolytic precipitation. In the course of this work zinc filings had been tried as a precipitant, but with the very dilute solutions employed electrolytic precipitation proved more satisfactory. The first experimental plant was erected at Siebenburgen for extracting gold from concentrate, and although the process was in successful operation as early as 1888 in other mining localities it was not until a number of years later, in 1893, that the Siemens-Halske process was introduced on the Rand goldfield of South Africa.

With the application of decantation to the unleachable portion of the slime, which had previously been allowed to accumulate, the problem at once arose of precipitating gold from large volumes of solution that were weak in both cyanide and gold. At that time the ordinary zinc-shaving method of precipitation did not give satisfactory results when used with very weak solutions. The Siemens-Halske electrolytic process, therefore, came into general use for precipitating the solutions from slime treatment.

In the Siemens-Halske process, iron anodes $\frac{1}{8}$ to $\frac{1}{4}$ inch thick, and lead-foil cathodes about 0.00032 inch thick were used. In general, the anodes and cathodes were set vertically and about $1\frac{1}{2}$ inches apart. There was considerable variation in the size and arrangement of the anodes and cathodes. At the Worcester plant they were 7 ft. long by 3 ft. wide, but in later installations, to facilitate handling, they were made smaller. The anodes were enclosed in sacks of textile material for the two-fold purpose of preventing short circuits and of collecting the prussian blue and iron oxide formed from the iron anodes.

The lead-foil cathodes were frequently cut in narrow strips for the purpose of increasing the surface. These were strung upon iron wires mounted in light wooden frames. Another expedient that gave still greater surface was to cut the lead into shavings similar to zinc shavings. These were packed into the space between the covered anodes. Various arrangements of the precipita-

*Abstract of paper presented at the twenty-eighth general meeting of the American Electrochemical Society in San Francisco, September 16-18, 1915.

tion units were tried, but the one most favored was to construct the containing box with alternate wide and narrow compartments, the narrow compartments serving for the down-flow of the solution, while the anodes and cathodes were suspended in the wide compartments, through which the solution had an upward flow.

This general arrangement will be recognized as being similar to that of the boxes used for zinc-shaving precipitation. The current density used was from 0.03 to 0.06 ampere per square foot of anode surface. The aim was to obtain a coherent plating of the gold upon the lead cathodes. After sufficient gold had accumulated upon the cathodes (2 to 12% of their weight) they were removed, melted, and the gold recovered by cupellation, either locally or at a central reduction plant.

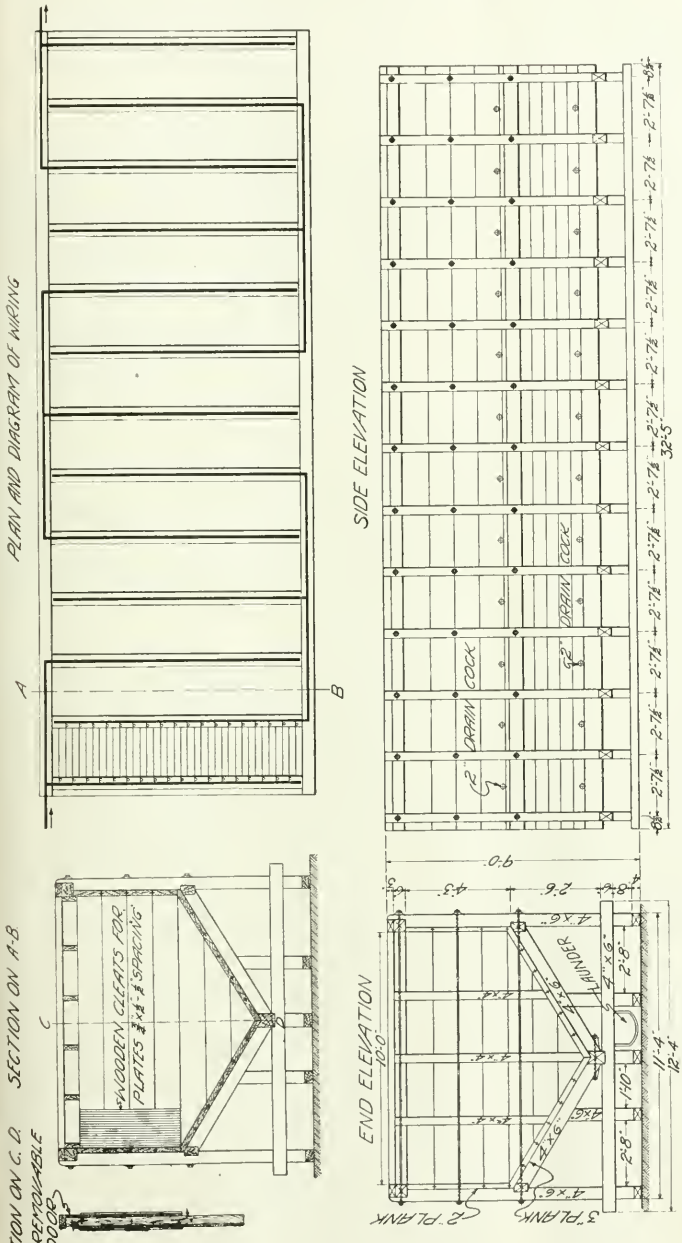


Fig. 1. Electrolytic precipitation-box, Virginia City, Nevada.

There was a long and bitter controversy on the Rand regarding the relative merits of zinc and electrolytic precipitation. In 1898, Betty, by means of a drip of strong cyanide solution at the head of the zinc-boxes, in conjunction with the zinc-lead couple, which was first proposed by MacArthur in 1894, demonstrated that precipitation by zinc could be used satisfactorily for solutions low in both cyanide and gold. After satisfactory precipitation of these dilute solutions by zinc became possible, electrolytic precipitation rapidly lost ground and finally was entirely superseded by zinc precipitation.

Minas Prietas. In 1899, Charles Butters, who had been identified with the introduction of the Siemens-Halske process in South Africa, assisted by two members of his former staff, H. T. Durant and E. M. Hamilton, developed a new electrolytic precipitation process, which was first successfully used for a number of years in connection with the cyanidation of a large deposit of pan-amalgamation tailing, and later of ore directly from the mine at Minas Prietas, Mexico.

The original plant for electrolytic precipitation consisted of six wooden boxes, 30 ft. long by 10 ft. wide and 5 ft. deep, having a slope of one inch per foot toward one side, to facilitate the removal of precipitate. The precipitation-boxes were divided by wooden partitions in-

to alternate wide and narrow compartments, 12 of each. The partitions were so arranged as regards the bottom that the narrow compartments throughout the box served only for the down-flow of the solution, while the wide compartments, in which were suspended the anodes and cathodes, served for the upward flow of solution. Each wide compartment was fitted with 18 lead anodes whose surface was coated with lead peroxide, formed by electrolysis in a special cell, and 17 cathodes composed of lead foil, cut in strips, strung upon wires supported by wooden frames similar to the cathodes used with the Siemens-Halske process. The current was supplied by two dynamos, each capable of developing 250 amperes at 30 volts, feeding into copper bus-bars $1\frac{1}{4}$ by $\frac{1}{4}$ inches laid on top of the boxes. In order to insure good contacts, the wires leading from the individual anodes and cathodes were soldered to the bus-bars, mercury-cup contacts having proved unsatisfactory. The solution passed through three sets of boxes, each set comprising two boxes set in tandem. One set of two boxes was used for precipitating the solution resulting from sand treatment and two sets of four boxes for precipitating the solution resulting from slime treatment. The current density was so regulated that the metals were deposited as a flocculent precipitate which fell to the bottom of the compartments in the form of a fine slime, as in zinc-shaving precipitation, rather than as an adherent coating upon the cathodes as in the Siemens-Halske process. After a short period of operation, it was found that the precipitate did not all fall to the bottom of the box, but that part of it formed a loosely-adherent mass on the cathodes. This necessitated washing and shaking of the cathodes when it was desired to make a complete clean-up. It was soon apparent that the fragile lead-foil cathodes could not long withstand such treatment. Investigation resulted in abandoning the lead-foil cathode in favor of a cathode made from ordinary tin-plate, which possessed the necessary strength and from which the precipitate could be readily brushed without removal of the cathodes from the containing box.

The pan-amalgamation tailing cyanided at this plant resulted from the treatment by raw pan-amalgamation of a comparatively simple silicious silver-gold ore. After the tailing deposit had been exhausted, the low-grade ore from the mine was treated. The sand was treated by percolation and the slime by agitation, natural settlement and decantation. The volume of the solution precipitated varied as did also its metal content. The proportions of cyanide and alkali were less variable, but by no means constant. Below are given average figures covering two months' operation, for solutions resulting from sand treatment when pan-amalgamation tailing was being treated. Average amount of solution precipitated per 24 hours, 216 tons. Current density 0.55 amperes per square foot of anode surface. The voltage across the anodes and cathodes varied in the different compartments, but averaged about 3. The head solution, or solution entering the precipitation boxes, contained: 0.147 oz. gold per ton; 3.51 oz. silver, and 0.0792% cyanide in terms of potassium cyanide. The tail solution or solution leaving the electrolytic precipitation boxes contained 0.013 oz. gold per ton, 0.29 oz. silver, and 0.0938% cyanide. The gain in cyanide was 0.0146%. As 1.2 tons of solution was used in treating each ton of sand, the cyanide apparently regenerated amounted to 0.35 lb. per ton of sand. The percentage of gold precipitated was 91 and the percentage of silver precipitated was 91.7. No attempt was made to lower the gold and silver in the tail solution, as none of it was used for final washes.

The following are average figures covering the same two-month period for the precipitation of solution resulting from slime treatment: Average amount of solution precipitated per 24 hours, 480 tons. Current density 0.3 ampere per square foot of anode surface. The voltage across the anodes and cathodes averaged 2.6. The head solution contained: 0.055 oz. gold per ton, 1.45 oz. silver, and 0.0409% cyanide. The tail solution contained: 0.0067 oz. gold, 0.15 oz. silver, and 0.0527% cyanide. The gain in cyanide was 0.0118%. As 4 tons of solution was used for each ton of slime, the cyanide apparently regenerated amounted to 0.94 lb. per ton of slime. The percentage of gold precipitated was 88 and the percentage of silver 89.6. When the solution flow was cut down to two-thirds normal, the tailing contained 0.0025 oz. gold and 0.06 oz. silver per ton. The regeneration of cyanide was doubtless greater with the solution resulting from the treatment of the slime on account of the greater proportion of copper contained. When treating ore directly from the mine containing little or no copper, the regeneration was not sufficient to be detected by ordinary titrations.

San Sebastian. The original electrolytic precipitation plant installed at Butters' Salvador Mines, at San Sebastian, Salvador, was similar to the Minas Prietas plant. However, it was found necessary to modify the practice in several particulars. The two wooden containing boxes were 30 ft. long, 10 ft. wide, and 4 ft. 8 in. deep. The bottom was given a slope to one side at the rate of one inch per foot. Each box was divided into 12 compartments, 10 of which were used for precipitation, the last two merely serving as settlers. Each compartment contained 25 anodes and 24 cathodes. The anodes were rolled lead plates $\frac{1}{2}$ inch thick, 22 in. wide, and 48 in. long. For some time the anodes were peroxidized in a special cell using an electrolyte consisting of 1% of potassium permanganate and 2% sulphuric acid; but later untreated lead plates were used. At first tin-plate cathodes similar to those used at Minas Prietas were tried, but difficulties arose that made it necessary to abandon the tin-plate cathode. The original intention was to deposit gold and copper as a non-adherent slime, as at Minas Prietas, but despite the fact that a higher current density was used the gold and copper were deposited upon the cathodes as a firmly adhering coating. The predominating metal in the solution at Minas Prietas was silver, but at San Sebastian it was copper. The well-known fact that silver is prone to give non-adherent coatings, while copper has a strong tendency to give ad-

herent coatings, seems to offer a ready explanation of the difference in behavior of the precipitated metals at the two plants. The removal of the strongly-adherent copper-gold plating from the tin cathodes presented a most difficult problem. Various expedients for removing it were tried, such as heating the cathodes with a gasoline

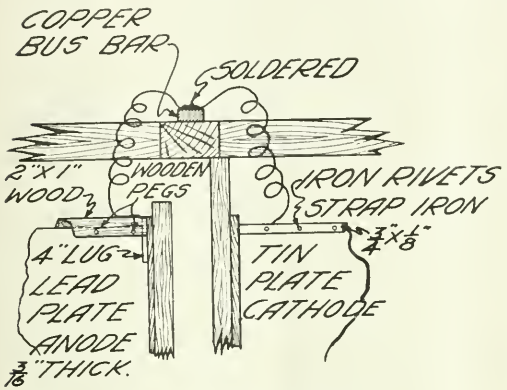

FIG. 2. ELECTRICAL CONNECTIONS.

torch, scraping and pounding them, etc. After these various heroic measures had proved ineffective, it was decided to return to the lead-foil cathode cut into strips, as used in the Siemens-Halske process. When it was desired to clean-up, the lead-foil strips were removed, ground, and shipped to smelters for the separation of the metals. The current was supplied by a belt-driven dynamo giving 450 amperes at 30 to 35 volts. The current density was 10 amperes per square foot of anode surface, and the voltage across the anodes and cathodes in each compartment was 4 to 4½.

This general practice was continued until C. P. Richmond modified it so that the metals could be separated locally.* The lead-foil cathodes were replaced by sheet-lead cathodes $\frac{1}{16}$ in. thick, 22 in. wide, and 48 in. long, so arranged that they could be readily removed from the containing-box. To this end, the connecting wires for the cathodes, instead of being soldered to the copper bus-bars, were clamped by wing-nuts in split studs screwed into the bus-bars.

The wires from five anodes and cathodes of opposite compartments were laid in each slot and a tight connection secured by screwing down the wing-nut. The studs were spaced 19 inches apart and six of them connected the cathodes of one compartment to the anodes of the adjoining compartment. By this arrangement it was possible to remove any of the cathodes without interrupting the flow of current or solution. At San Sebastian it was found advantageous to operate so as to keep the concentration of the copper down to a point where it did not interfere with gold extraction, and precipitate the remaining gold by zinc shaving. This was done despite the fact that zinc was said to interfere with electrolytic precipitation in South Africa. The solution leaving the electrolytic-boxes was divided between two zinc-boxes each 22 ft. long and having compartments, 2 ft. by 1 ft. and 2 ft. deep, filled with zinc-shaving. The material was a high-grade gold ore containing considerable pyrite and sufficient copper left in the soluble form after the roast preceding cyanide treatment, to occasion trouble in cyanidation unless electrolytic precipitation were used. The average gold-content varied, but at the time that electrolytic precipitation was in use it ranged from 2 to 4 oz. per ton. The soluble copper varied from ½ to 2½ lb. per ton. The ratio of gold to

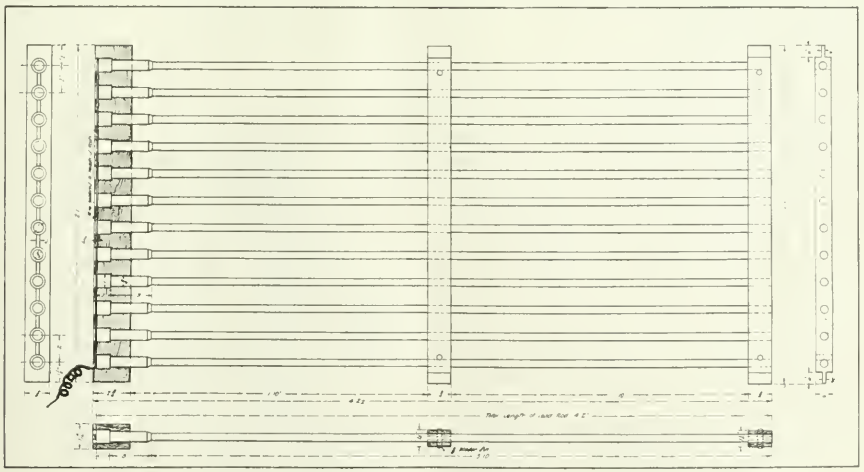

FIG. 3. LEAD-ROD ANODE.

*For details of the electrolytic separation of the copper-gold deposit, see 'The Electrolytic Precipitation of Gold, Silver, and Copper from Cyanide Solutions.' By G. H. Clevenger. Vol. XXVIII, Trans. Amer. Electro-Chem. Soc.

copper in the electrolytic deposit ranged from 1:7 up to as high as 1:25, but generally was between the limits of 1:9 and 1:14. The average results of two months, taken at random, will give a general idea of the performance. During this period there was treated 45 tons of ore daily, averaging 2.27 oz. gold per ton. Approximately 150 tons of solution was precipitated daily. The average content of the head solution was: gold 0.79 oz. per ton; copper, 0.075%; cyanide, 0.118%. The average content of the tail solution from the foot of the zinc-box was gold 0.004 oz. per ton, copper 0.048%, cyanide 0.154%. The percentage of gold in the deposit at the head of the electrolytic-box was about 7; at the foot of the box it was about 3. The current-density was 1 ampere per square foot of cathode surface. The voltage across the anodes and cathodes of each compartment was 4 to 4½. During the treatment of the ore there was consumed 7.2 lb. of sodium cyanide per ton. There was precipitated in the electrolytic-boxes 1.5 lb. of copper and apparently there was regenerated 1.92 lb. of cyanide, in terms of potassium cyanide, per ton of ore treated. Eighty to 90% of the gold and most of the copper was precipitated in the electrolytic-boxes. Passage through the zinc-boxes brought the total percentage of gold precipitated up to 99.5. The zinc-boxes precipitated little copper despite the fact that the solution invariably contained copper at this point. Under normal conditions the percentage of copper in solution remained nearly constant, any increase through contact with the ore being precipitated by the electrolytic-boxes. When the copper accumulated in the solution, as was sometimes the case through treating ore containing an unusually high proportion of copper, the bad effect was at once noted upon the gold extraction.

Virginia City. In the installation of the electrolytic precipitation plant at Virginia City, Nevada, Chas. Butters & Co., Ltd., had the benefit of the experience gained at the plants previously installed by them. This resulted in several important improvements. Originally there were nine boxes, similar to that shown in Fig. 1, the idea being to use three of these boxes for precipitating copper from a preliminary wash by sulphurous acid, which, when the plant first began operations, was intended to precede cyanide treatment. The other six boxes were to be used for precipitating gold and silver, together with any copper remaining from the cyanide solutions. The preliminary treatment with sulphurous acid was finally abandoned and direct cyanidation practised. The precipitation practice finally evolved for the cyanide solution was to use four of the boxes in pairs of two arranged tandem, the solution issuing from the first set of boxes passing through the second set. As at San Sebastian, electrolytic precipitation was followed by zinc-shaving. The zinc-box was improvised by placing screens in the bottoms of a number of the compartments of two of the discarded electrolytic-boxes.

At Minas Prietas the method of handling the precipitate was rather crude, as a part of the cathodes and anodes had to be removed to give access to the bottom of the boxes during the clean-up. At Virginia City this feature of the process was greatly improved by constructing the precipitating boxes with hopper bottoms. In each compartment where one of the sloping sides of the hopper joined the vertical side of the box was placed a valve through which the bulk of the solution contained in the box could be drawn prior to sluicing out the precipitate. At the apex of the hopper in each compartment was placed another valve through which the slime could be sluiced to a launder that conveyed it to a small concrete tank equipped with a mechanical agitator, whence it was pumped by a centrifugal pump into an ordinary distance-frame and plate type of filter press. After drying, the precipitate was sampled and shipped to the Selby Smelting Co. Later, a refinery was built. The precipitate, after retorting to recover mercury, and after the addition of the proper admixture of fluxes, was melted in graphite crucibles heated in specially designed tilting furnaces. With the arrangement described above it was not necessary to disturb the anodes or cathodes when cleaning up. Each box had 12 large compartments, in which were suspended 18 peroxidized sheet-lead anodes ¼ inch thick, 25 in. wide, and 48 in. long, and 18 tin-plate cathodes of the same size. Sheet aluminum cathodes were also tried. Later, an anode composed of lead rods was used. The advantage of this anode was that it could be made locally from scrap lead or old anodes. The Wood dynamos, each giving 500 amperes at 50 volts, and direct connected to an induction motor, furnished the current.

The character of the ore treated at this plant varied greatly. Originally it was built to treat a large accumulation of tailing resulting from the treatment of Comstock ores by pan-amalgamation. Later Comstock ore and concentrator tailing, and ore from the Tonopah district, were treated. The treatment of outside ore began before the exhaustion of the tailing, so that at times there was a varying mixture of tailing and ore. The pan-amalgamation tailing had been re-treated a number of times by the same process and was, therefore, very low grade. It contained copper, mercury, and chlorides as a result of the chemicals added during pan-amalgamation. The tonnage and metal content of the solution varied considerably, but the following is an average of the results obtained over a period when treating pan-amalgamation tailing exclusively, and precipitating 474 to 668 tons of solution daily. There was no distinction made between the solution originating from the sand and slime treatment, the two being combined for precipitation. The average content of the head solution per ton was: gold 0.033 oz., silver 0.78 oz., no record of copper determinations, cyanide 0.046%, protective alkali 6 points. The tail solution from the electrolytic-box contained: gold 0.01 oz., silver 0.22 oz., cyanide 0.066%, protective alkali 4 points. The zinc-box tails contained: gold 0.003 oz., silver 0.03 oz. The current density was 0.245 amp. per sq. ft. of anode surface. The voltage across the anodes and cathodes in each compartment was 3.1. The average content of the head solution when treating a mixture of Tonopah ore and pan-amalgamation tailing was: gold 0.055 oz., silver 3.15 oz., cyanide

0.18%, protective alkali 10 points. The tail solution from the electrolytic boxes, when precipitating 432 tons per 24 hours, contained: gold 0.02 oz., silver 0.60 oz., cyanide 0.18%, protective alkali 10 points. The current density was 0.245 amp. per sq. ft. of anode surface. The voltage across the anodes and cathodes in each compartment was between 3.1 and 3.2.

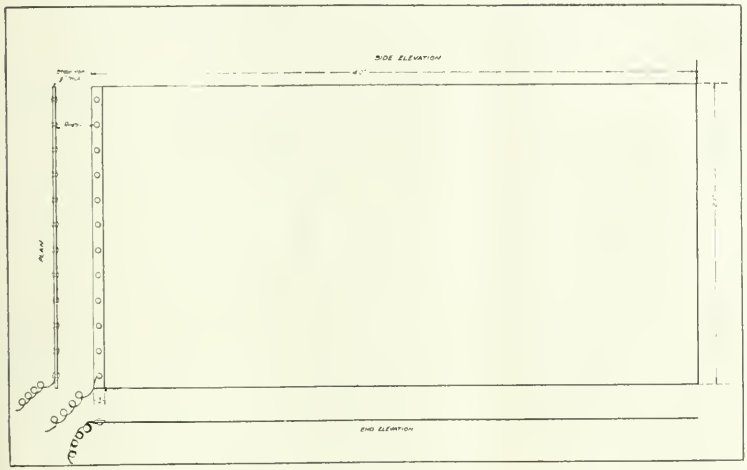

FIG. 4. TIN-PLATE CATHODE.

EL RAYO. The equipment installed at El Rayo, Mexico, followed rather closely the lines of that used at San Sebastian, and consisted of one wooden box 10 ft. wide by 20 ft. long, 4 ft. deep on one side and 5 ft. deep on the other, with the usual arrangement of wide and narrow compartments. In each of the seven compartments were fitted 25 sheet-lead anodes, 20 in. by 40 in. and $\frac{1}{4}$ in. thick. Alternating with the sheet-lead anodes, there were 24 sheet-copper cathodes, 20 by 40 in. and 1/32 in. thick. Electrical connection of the anodes and cathodes to the bus-bars was made by means of lead plugs cast onto the plates, to which were soldered copper connecting wires. The current was supplied by a generator giving 500 amperes at 50 volts.

At the time that this installation was made, zinc-dust precipitation of the gold and silver was giving satisfactory results. A change in the character of the ore indicated that trouble might arise through a greatly increased proportion of copper. It was, therefore, planned to continue to precipitate with zinc and depend upon electrolytic precipitation to keep the copper in solution down to a concentration that would not interfere with cyanide treatment.

ANODES. Iron anodes were used with the Siemens-Halske process in South Africa, but lead, with a few exceptions, has been used in American practice. Various other anode materials have been tried, but, everything considered, lead is the most satisfactory. One important advantage that lead has over many other anode materials is that it has a certain salvage value after it has served its useful life as an anode. It has been used both plain and peroxidized, but in general the peroxidized anodes have had the longest life. Many investigators have reported certain anodes as being satisfactory when used in cyanide solutions, but these tests carried on in a small way have always covered entirely too short a period of time. The fact that an anode will stand up for two or three days of continuous operation in no way signifies that it will be satisfactory for a period of operation sufficiently long to make its use commercially economical. Experiments with Acheson graphite have been most disappointing, notwithstanding the favorable reports made by other investigators who have tried this

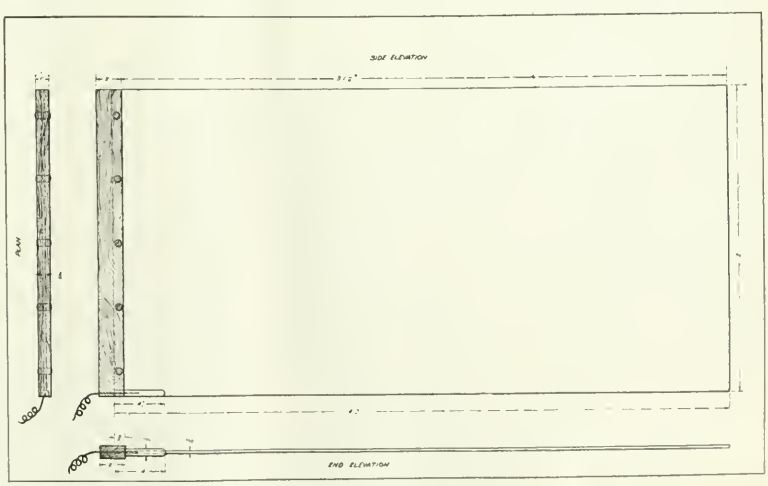

FIG. 5. SHEET-LEAD ANODE.

material in a small way for short periods of time. The graphite anodes gradually become mushy and soft and finally are useless. The reason for the failure of the graphite anode is not clear, but at one time I thought that it was due to disintegration of the binding material used in the original carbon plates from which the graphite plates were made. In other words, the graphite resulting from the carbonaceous binding material of the original carbon plate does not appear to form a strong union with that resulting from the carbon proper of the plate.

The sheets of lead, after cutting to the desired size, are thoroughly cleaned and in one corner or on the two opposite corners of the short dimension of the sheet is cast a special connecting lug, $\frac{1}{2}$ inch diam. by 4 in. long, by means of a special iron mold that clasps the plate firmly at the point where the lug is to be attached. The lugs are cast from lead to which has been added a small amount of tin, to lower its melting point. The temperature of the lead used in casting the lug should be such that it does not melt through the lead sheet, but still is sufficiently hot to form a thorough union with the lead sheet. A tongued wooden supporting strip is attached to the top of the plate by means of wooden pins. The whole arrangement is shown in Fig. 5.

Fig. 3 shows the detail of the lead-rod anode.

The lead-rods are cast in special iron molds, observing the usual precautions for preventing the oxidation of lead during melting and the obtaining of a clean, smooth casting free from holes or spongy spots. Twelve of these rods supported in strips of pine drilled to receive them at the bottom, at the centre, and at the top, comprise an anode. The bottom and centre strips are 1.75 by 1.25 in., and are kept from shifting by means of wooden pins that engage the two outside rods. These also serve to prevent short-circuiting of the tin-plate cathodes, which have a strong tendency to buckle. The top strip, $2\frac{3}{4}$ by $1\frac{3}{8}$ in., is counterbored to receive the large ends of the rods, and supports the whole weight of the anode. Electrical connection to the individual rods is made by soldering to them a No. 10 copper wire, which rests in a groove at the top of the strip. The continuation of this wire serves as the means of connecting the anode to the bus-bar.

The method of peroxidizing the anodes varied at the different plants. This operation was performed in a separate cell where a few anodes at a time were treated. The first step was to clean and brighten thoroughly the surface of the lead with a scratch-brush. At Minas Prietas a 1% potassium permanganate solution was used and a current density of 1 amp. per sq. ft. The time was one hour or longer. During the operation the strength of the solution was frequently tested with a standard solution of ferrous sulphate, fresh permanganate being added to keep the solution as near 1% as possible. At San Sebastian various combinations were tried, but the practice that met with the most favor was to use an electrolyte containing 1% of potassium permanganate, 2% sulphuric acid, and a current density of $2\frac{1}{2}$ amp. per sq. ft. The time of treatment was 6 hours. In passing, it is well to mention that it has been found in certain of the electrochemical industries that a denser and more satisfactory coating of the peroxide is formed if the operation is performed in an alkaline solution.

At Virginia City the peroxidized lead anodes had a life of about one year. At San Sebastian, on account of the higher current density, the life was 8 to 12 months. At Minas Prietas the life was in some cases considerably over a year.

Cathodes. The lead-plate cathodes used at San Sebastian were constructed similar to the anodes, except that the sheet lead used was thinner.

An interesting feature of the lead cathodes used at the Reliance mill was that they were not ordinary rolled sheet lead, as had been previously used elsewhere for both anodes and cathodes, but were plates cast upon an inclined machine at the Trail smelter. It was said that one man could make 500 cathodes in a shift.

The tin-plate cathode was made from medium-weight tin-plate, as shown in detail in Fig. 4. A piece of strap iron $\frac{3}{4}$ by $\frac{1}{8}$ inch, the length being the same as the width of the plate, was riveted to the top. The connecting-wire was introduced between the plate and strap-iron in such a manner that one of the rivets clamped it firmly in place. Fig. 6 shows the tool used in removing the portion of the deposited metals which adhered to the cathodes. The double brush was used at intervals for removing the slightly adherent deposit. The manner of using was to set it over the cathode so that a brush was bearing on either side of the cathode, when the whole tool was pressed downward until the brushes had reached the bottom of the plate; this operation was repeated until the whole surface of the plate had been covered. When it was desired to make a complete clean-up, especially if the plates were old, it was necessary to remove them entirely from the box and scrape them with the triangular scraper, shown in Fig. 6.

The By-Products have always presented a serious problem. In the Siemens-Halske process, the Prussian blue, formed as a result of the attack on the iron anodes, had to be subjected to special treatment for the recovery of the cyanide and gold. The disadvantages arising through the separation of calcium salts, which deposited upon the anodes and cathodes and in the bottom of the box, was early noted in the application of the process. It has been variously estimated that from 0.6 to 25% of the gold had to be recovered from the by-products in the Siemens-Halske process.

At Minas Prietas, the precipitation of calcium salts was especially troublesome, and owing to the method of operating in which the non-coherent deposit of the metals was collected in the bottoms of the boxes, all of this eventually became intermingled with the precipitate. At this time the calcium salts, chiefly the carbonate, formed a large proportion of the precipitate. This made the precipitate more difficult and costly to smelt.

Lower current-density lessens the formation of the lime precipitate, but does not entirely eliminate the difficulty. In the course of time the lead anodes disintegrated so that they had to be discarded. At first

these were shipped to lead smelters, but later they were re-melted locally, and after the separation of the dross, which had to be shipped to the smelter, were cast into slabs that were rolled by a special set of rolls into sheets which were used in making new anodes.

At San Sebastian, where the gold and copper formed a coherent deposit upon the cathodes, it was possible to keep the deposit that accumulated at the bottom of the box separate from the deposited metals. However, the gold contained in this material was considerable, and at one time, when a considerable amount of it had been allowed to accumulate, it represented a great deal of money. The material more directly resulting from the disintegration of the anodes contained:

	%		
Lead	53.7	to	57.1
Copper	3.1	to	4.7
Gold	0.031	to	0.154

The fine material, or 'lime' as it was termed, contained:

	%		
Silica	8	to	10
Alumina	22	to	28
Calcium oxide	15	to	21
Lead	Not Determined		
Copper	5.9	to	6.9
Gold	0.322	to	0.363

A small blast-furnace and other equipment for refining was installed for treating the by-products, but on account of the high cost of coke and other supplies and the lack of skilled labor, it was generally found more economical to ship this material to smelters in the United States. No attempt was made to reclaim the anodes.

At Virginia City the conditions were much the same as at Minas Prietas. A lower-grade precipitate was invariably obtained from the electrolytic-boxes than from the zinc-boxes on account of the calcium precipitate. At one time, as the result of careful sampling and assaying, it was estimated that the anodes contained about 10,000 oz. silver. This came about by reason of the fact that the solutions contained chlorine. The source of this in the tailing was the salt added during pan-amalgamation and, in the Tonopah ore, was due to the occurrence of part of the silver as chloride. The presence of the silver as chloride in the anodes was proved by solution in ammonia and the regular qualitative tests. In the earlier operation the disintegrated anodes were shipped to the smelter; but later it was found that by careful heating in suitable pots the greater part of the metallic lead could be liquated, leaving most of the gold and silver in the dross, which was shipped to the smelter and the lead cast into rods that were mounted in wooden supports and used as anodes.

Cost of Installation and Operation. The cost of the six electrolytic precipitation boxes at Minas Prietas, Mex., was as follows:

Box construction	$10,000
Dynamos	3,000
Lead anodes	4,455
Tin-plate cathodes	300
Wiring, switchboards and instruments	1,000
Labor	1,000
Incidentals	250
Total for six boxes	$20,005

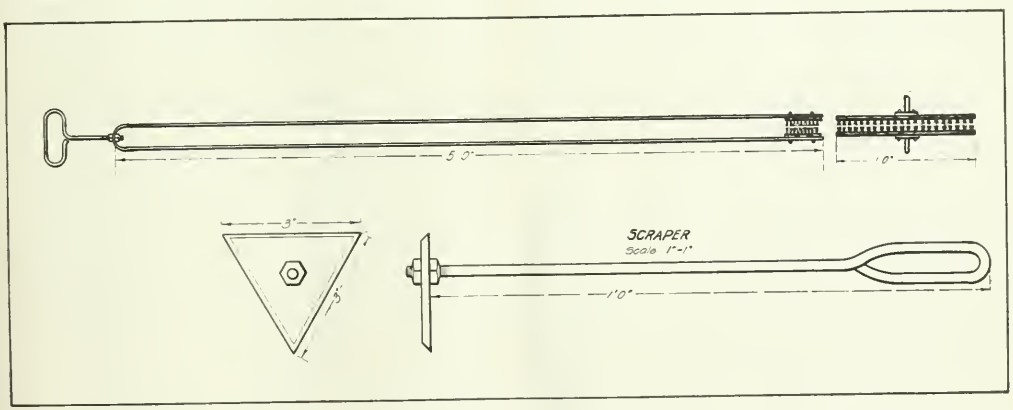

Fig. 6. Tools for cleaning cathodes.

At Virginia City, Nev., U. S. A., the cost of six standard boxes was as follows:

Box construction	$6,000
Dynamos	4,075
Lead anodes	4,080
Aluminum cathodes	*1,598
Wiring, switchboards and instruments	1,000
Labor	1,500
Incidentals	250
Total for six boxes	$18,503

*Tin-plate cathodes also used.

The only costs available for electrolytic precipitation are those given below, which are the average for six years' operation of the Minas Prietas plant.

Power	$0.083
Labor	0.037
Supplies	0.031
Depreciation	0.040
Total per ton of ore	$0.191

Mining in Colorado

By GEORGE J. BANCROFT

The phenomenal rise in tungsten prices from $4 to $40 per unit has produced a new variety of mining magnate. Denver is used to 'silver kings' and 'copper kings,' while gold potentates are always drifting in, but now the bell-hops at the big hotels are learning to say with bated breath: "There goes Smith, the tungsten king." The Boulder county mines are proving reliable producers of tungsten. Leadville and the San Juan have produced a little tungsten, but the orebodies are few and far between. Furthermore the tungsten is apt to occur in small streaks in veins that are chiefly valuable for other metals, so that, as a rule, it is not worth while to equip the mills to separate out a small amount of tungsten. A small production is made by hand-sorting in some mines. In the Boulder county mines the tungsten is disseminated through the vein and occurs in relatively large ore-shoots, considering that the veins are narrow for the most part, running from knife-blade seams up to three feet wide. Of course, there are some pockets that are much wider, say 10 ft., but the average width is 12 inches. The ore-shoots are relatively long and deep as compared with most tungsten mines. Several stopes are 300 ft. measured along the vein, and an average ore-shoot would be perhaps 75 ft. wide and 1 ft. thick. With tungsten at $40 per unit one can readily see that very small veins can be worked at a profit.

It appears that the War has made a tremendous demand for tool-steel for turning out shells and gun-barrels. Tungsten-steel is the most efficient material for lathe-tools yet discovered, being said to be seven times more efficient than a good grade of carbon-steel. It has been reported that the German cannon are made of tungsten-steel, which was the reason they were superior to the guns of the Allies. It is thought that relatively little Boulder county tungsten goes to gun-manufacturers. It nearly all goes to steel-makers that make a specialty of tool-steel. The Boulder county ore is unusual in being the pure tungstate of iron, ferberite. Generally tungsten occurs associated with manganese; wolframite, the tungstate of iron and manganese, and hübnerite, the tungstate of manganese, are the common ores. These minerals generally are found in concentrated isolated masses. In Boulder county the ferberite is disseminated through the vein-matter and most of it requires concentration before shipping.

In Cripple Creek there have been important discoveries in the Last Dollar, Cresson, Jerry Johnson, Portland, and other mines, but the chief attention is being given to the developments at great depth. So far, the two deepest shafts, namely, the Vindicator and the Portland, indicate that the ore persists to the greatest depth attained, namely, about 1800 ft. The Vindicator will soon be driving on the 1900 and 2000-ft. levels and the results will be awaited with interest. The 1800-ft. level has proved profitable in both the Portland and the Vindicator. As mentioned in previous discussions, the large and phenomenally rich concentrations of ore at Cripple Creek appear to be isolated occurrences. A level that happens to uncover one of these erratic orebodies becomes at once a very important working, but the fact that the deepest levels are up to the average is all that can be expected. It is said that a phenomenal orebody has been found going below the 1800-ft. level, north, in the Vindicator and there are also persistent rumors of a remarkable strike on the Portland at 1800 ft. These stories have not been confirmed officially as yet. Official reports tell us, however, that the ore thus far developed on the Vindicator 1800 is nearly twice as long as that developed on the 1600-ft. level, though of lower grade; and the Portland 1800 shows that there was no diminution in the value of the orebodies. So the outlook at Cripple Creek has well founded anticipation of a long and productive life.

The dredges have had a prosperous season. The new dredge on the Derry Ranch placer has been running only a month, but it is said to have produced $19,000 during October. Indications at present are that the total value of metals produced in Colorado during 1915 will be considerably in excess of that produced in 1914. The question of tonnage is not so well settled, but is likely to show an increase. The largest single factor in stimulating increased returns has been the high price of zinc. J. F. Welborn, the president of the Colorado Fuel & Iron Co., takes an optimistic view of the iron situation in Colorado, but deplores the over-development of the coal mines. He says in part: "The railroads are buying more freely than at any time within two years, and the demand is improving in other lines manufactured by our plant at Pueblo; we have received a number of orders for shipments abroad, including heavy exports to China. Agricultural development throughout the country is giving an impetus to orders for wire fencing, nails, and a number of other articles used in this industry."

COLOMBIA has an area of 438,000 square miles, which is larger than all the Atlantic Coast states from Maine to Florida, and has a population of 5,500,000, while Bogota, the capital, has 125,000. It has a coast 1600 miles long on the Caribbean Sea and 1500 miles along the Pacific, a total coast-line of 3100 miles. Only about 700 miles of railway is reported in operation, principally along the Caribbean Sea but extending also into the mountains. Transportation centres around the river Magdalena, which flows northward into the Caribbean; it is navigable by large vessels for 600 miles and for smaller craft 300 miles farther. Up this river foreign merchandise enters the country, the greater part of the national products coming from within a short distance of the river. Harbors on Colombia's Caribbean coast are only 1400 miles from New Orleans and but 1900 miles from New York. The country is known to be rich in deposits of gold, silver, platinum, oil, iron ore, copper, coal, and emeralds. There has been no revolution for 13 years, and the present political situation is excellent. In 1913, Colombia took 26% of her imports from and sent 55% of her exports to the United States.

Mining in Arizona

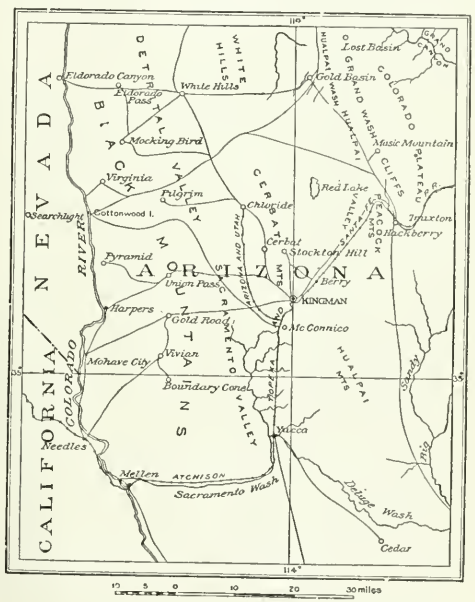
By CHARLES F. WILLIS

The leading feature of mining in this State during the past month has been the strike in the Clifton-Morenci district. The opposition to the strikers is evidently being maintained by the managements in a determined spirit, as the question involved does not alone influence the district in which the strike is taking place, but the entire region. Conditions at the various mining centres in Arizona are extremely dissimilar. At Bisbee high wages are paid and the labor is largely American; at Ray the scale of wages for Mexican labor is also high, thereby attracting the more intelligent class of Mexicans. However, at Clifton only the cheaper class of alien labor has been used, owing to the narrow margin of profit derived from these particular mines.

The abnormal condition of the copper market, its present prosperity, coupled with the low wage-scale of the Clifton-Morenci district allowed the organizers of the Western Federation of Miners an opportunity to start trouble. Heretofore the unions had been of but little influence in the mining districts of Arizona; there are unions in practically every district, but the number of organized men has been small as compared with those unorganized. Thus the immediate problem is not the adjustment of grievances on the part of the employees, but merely a recognition of the Western Federation. Natural circumstances seem to favor the mine-operators because the condition of labor at this place is such that the strikers cannot stand for any great length of time the non-payment of wages; while they get some support from the rest of the unions within the State, it is comparatively small because of the inconsiderable number of union men in the other districts.

This strike is but the climax of a struggle for political dominance that has been going on for some time between capital and labor. Arizona has had a reputation for freak laws regulating operations involving capital, and while the laws are no more freakish than in many other states, the publicity that has been given them is such as to cause outside capital to fear to enter the State, not so much for what has happened as for what may happen. Ample evidence has been offered that organized labor in the State can pass any laws that it so desires, and one side of the present struggle represents an effort to weaken labor and to prevent it from getting a firmer hold upon industrial conditions. There is little doubt that this fight will be fought to a finish. The operators have already incurred their greatest loss with the shutting-down of their plants, the caving of the mines, and the 'freezing' of their smelters. They show no haste and, in fact, little desire to meet with the employees.

While internal troubles are bad, border conditions are worse. The recognition of Carranza by the United States government has led to considerable turmoil in the territory held by Villa supporters, followed by the confiscation and damage of American property. As the greater part of Sonora bordering on Arizona is held by Villa, who is now in a bad way, American lives and property are not safe. The occupation of a border town by either one army or the other assures them revenue from export and import taxes, whereas the possession of an inland town assures no income. Moreover, the border towns pay in American money. It is evident that the



MOHAVE COUNTY, ARIZONA.

Mexicans in Sonora are not fighting for any principles or for any particular leader; it is either a case of being in an 'army' or going hungry, so they are willing to join any army that can ensure them, either by its financial condition or by its points of vantage, that they will receive their *frijoles* and *tortillas*. As the method of transportation from one place to another is either on foot or through United States territory, Carranza hopes to get control of the border by being allowed transportation on the railroads through the United States. If such privilege accompanies recognition, and an embargo is placed against those opposing him, conditions will improve.

Naco, on the railroad leading to Cananea, has been a particularly rich prize, and the army in control has

levied duty upon duty on both imports and exports. For this reason Cananea has rather been left alone and allowed to work with little destruction of property other than the burning of bridges and railroads, but the recognition of Carranza has caused the shutting-down of the Cananea property, which will probably be followed by confiscation on the part of the Villa troops.

In spite of both international and internal troubles, mining in this State is progressing. Excitement has been caused by the finding of indications of oil in the Tonto Basin. For some years oil has been suspected in the Tonto Basin country, and drilling has been going on in a rather desultory manner, many companies starting with insufficient capital and quitting before really finding out whether oil existed there in a commercial way. At a depth of 1200 ft. red shale has been cut and after penetrating 300 ft. more, the water showed distinct signs of gas with an oil scum on the surface. While it is not known yet whether anything of importance will be developed, this has not hindered local excitement.

The recent trip through Arizona of a buyer of tungsten ores has lead to an intensive stimulation of tungsten production, with the consequent immediate planning of mills and the buying and selling of tungsten properties. Globe has attracted attention by its properties in Powers gulch; in Mohave county, attention has temporarily turned from a gold boom to the operation of the Williams tungsten mine and mill near Kingman. In the Whetstone mountains a new company, the American Tungsten Co., is working several properties, while the Primos Chemical Co., a large purchaser of tungsten ore, is also operating nearby. The Tip Top mine, in Yavapai county, which for many years was worked as a silver mine, the tungsten ore being discarded, is now planning to work the dump, and will be considered as a tungsten mine with silver as a by-product. The prices reported for tungsten ores are seemingly fabulous; one report says that it sells for $28 per unit, although on the same day a report was received from another part of the State that the same company offered $35 per unit. Whichever price is correct, it is evident that the market for tungsten ores is lively.

The same buyers desire also molybdenum and vanadium, quoting $3500 per ton for 90% molybdenite ore. Molybdenite in Arizona is almost always associated with copper, and separation is difficult. Such a high price, however, offers incentive to investigation.

The Jerome district is particularly active. The Arkansas & Arizona Co., idle for nearly a year, has commenced re-timbering the shaft and installing machinery for unwatering. The United Verde Extension is now making regular shipments to Douglas, and the opinion of the early investors has been fully justified. The mine of the Hull Copper Co., although of undoubted value, has been shut-down owing to a suit against the company by G. W. Hull, the president of the company. The result has been an extremely low quotation for the Hull mining stocks. The Jerome Verde has awakened interest, doubtless because of the constant success of the United Verde Extension, the two properties being adjacent. The United Verde Extension for some time has been negotiating to gain control of the Jerome Verde since the release of the option, which expired in the month of June. This property was being developed through the lower workings of the United Verde Extension.

A mild boom has been in progress at Oatman following the sensational discoveries in the Tom Reed and United Eastern mines. Many claims have changed hands and new companies organized within the past few months; mills are in course of erection. The fact that a vigorous boom has not matured is evidence that the public is not as easily stampeded as would have been the case a few years ago. Construction work on the United Eastern mill is being advanced rapidly, the initial plant having a daily capacity of 200 tons. Crushers are used instead of stamps, the ore going from the crushers to tube-mills, then to the cyanide annex. In the Black Eagle workings of the Tom Reed, an ore-shoot has been opened to a depth of 400 ft. and recent development work has disclosed 32 ft. of ore of $20 per ton, with 14 ft. of it close to $30 per ton. Although the Oatman district is renowned for its gold, its largest producer is the Golconda mine, a zinc property. The monthly output of this district is estimated as follows:

Golconda	$250,000	Gold Road	70,000
Tennessee	150,000	Champion	35,000
Tom Reed	100,000	Scattered	35,000
Copper Giant	100,000		
			$740,000

Later the United Eastern, the Golconda Extension, and many others will be added to the list.

The Inspiration Consolidated at Miami is to erect the largest Dorr thickening-tank, with a diameter of 200 ft. The largest hitherto has been at the plant of the Arizona Copper Co., at Clifton, a reinforced concrete tank 135 ft. in diameter. Nine sections of the Inspiration mill are now in operation and about 7000 tons is handled daily.

Although few reports are issued from the Bunker Hill mine in the Tombstone district, it is evident that things are progressing satisfactorily and rapidly. In early days Tombstone was considered a great mining centre, and it has been necessary in the past few months to put up more dwellings to house those living in the district. Dr. Emil Grebe, a hard-working and conscientious mining man, has charge of the Bunker Hill.

The Las Guigas placers, about 60 miles southwest of Tucson, are again active. It is reported that this ground averages $1 per cubic yard, but it remained undeveloped because of the high cost of water. The Clark agitating-sluice is being tried, which is somewhat similar in operation to the Dorr classifier. Although not a dry machine, it works with a small volume of water. For fifty years these placers were worked in a desultory manner by Mexicans and Indians, using batea in the dry season and pan-rockers in the wet season. Bedrock is from three to ten feet; by the removal of the gravel and the panning of the ground beneath, many thousands of dollars have been extracted.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

To ENSURE that all connections in electric blasting are good, a galvanometer or circuit-tester should always be used.

THE NEW IRON COINS for replacing the German copper currency, which is being called in, are made of open-hearth steel with milled edge.

SQUARE-SET system of stoping at the Interstate-Callahan zinc mine, Idaho, has been changed to the waste-fill method. This resulted in a reduction of underground charges, and increased the metal-content of the mill feed from 20 or 22% to 27 or 30% zinc.

COBALT is highly suitable for electro-plating instead of nickel, according to researches on cobalt and its alloys at the Queen's University, Kingston, Ontario. Commercial applications have given excellent results, notably on automobiles.

QUICKSILVER METALLURGY has made few advances in latter years. Innovations are to be tried at New Almaden, California, consisting of a six-hearth Herreshoff roasting-furnace and hollow-glazed tile condensers. The latter is considered superior to the solid 9 or 12-in. brick arrangement, which absorbs considerable metal. Dumps of low-grade material are to be crushed in a ball-mill and concentrated on tables. Flotation may be tried on the slime.

IN BURKE QUARTZITE, a 6 by 8-ft. adit at the Gertie mine, Coeur d'Alene, Idaho, was driven an average of 311 ft. per month for a year. A maximum of 17 picked men was employed two shifts per day, and there were six holidays. A bonus of from $25 to $40 per man per month was paid for extra footage. The air-pipe for machines was 4 in. diameter; that for ventilation 15 in. The compressor was a good one. The blacksmith-shop was equipped for efficient work. Waste-cars were of 35-cu. ft. capacity, one horse hauling four. The cost of the work was $67,000, or, say, $18 per foot.

EXPLORATION of the New Cornelia property of the Calumet & Arizona Copper Co. at Ajo consisted of the following: Seventy acres of land was laid off in regular 200-ft. squares, and 84 diamond-drill holes were put down on the corners of these squares. These bores yielded cores and cuttings; the latter showed the geological and petrographical nature of the rock, and the former were assayed. Samples were taken every five feet, and a total of 9300 were taken. Besides the drilling of 23,097 ft., about 4000 ft. of test-pit work was done, which also was sampled every five feet, making 800 samples more. The pits were put down on the same co-ordinate points as the drill-holes, in order to check the accuracy of the drill-samples. Nothing was left to chance; 11,105 samples were taken altogether to prove the value of the orebody. In the 70 acres drilled, an orebody covering 61 acres was found, varying from 1500 to 2000 ft. long, 650 to 1500 ft. wide, and 120 ft. and over in depth.

UNDERGROUND LOCOMOTIVE HEAD-LIGHTS can be fitted with low-voltage concentrated-filament tungsten lamps in parabolic reflectors, with a decrease in trouble, increased light, and decreased breakage over the present carbon or regular tungsten filament. Two 30-volt, 100-watt tungsten-filament locomotive-headlight lamps can be burned in series with a resistance. The loss in current through the resistance is a small factor as compared with the gain in steadiness and brilliancy of illumination from the parabolic head-lights. The construction of this lamp is such that maximum strength of filament is obtained, an essential feature for such severe service.

ORE-VERTICALS are sometimes mentioned in the mining notes of our correspondent at Deadwood, South Dakota. In the stopes of some mines from which the ore has been completely excavated discolored seams may be observed. These are generally quite conspicuous, both on account of their slightly iron-stained appearance and on account of the resistant character of the material of which they are composed, the latter feature having frequently caused them to project from the softer, unmineralized country-rock. They may be most readily observed in the beds overlying the ore, as these are of slightly lighter color and of a more shaly character than those in which the ore itself occurs; but if carefully followed to the side or end of the stope may be traced downward into the underlying quartzite, shale, or dolomite, whenever mining operations have revealed the rock below the ore. These seams are known to the miners as 'verticals.' In a vertical there are two features to be distinguished: (1) the original fracture; and (2) the mineralization along or proceeding from that fracture. The original fracture is a result of rupture due to strains in the country-rock. It may have been a simple crack with no perceptible open space between the walls or a crevice an inch or more in width. Secondly, as a result of mineralization the fracture is often filled by silicious deposits, and sometimes stands out as a small ridge in softer material, or it may be lined with quartz crystals and not completely filled. Often it is not clearly distinguishable in the mass of the ore. As a result of the replacement of the country-rock on either side of the crevice, a sheet of hard silicious rock is formed which may extend for a considerable distance on either side of the fracture. If extensive it forms an ore-shoot; if slight a vertical. This vertical is often confused with the fracture, but it is important not to confound the two. The fracture admits the solutions and the orebody is formed by them. At times the vertical, which has resulted from the mineralization of a series of parallel fractures, occupies the entire roof of the stope, the space between the individual fractures having become more or less silicified. Simple fractures are generally vertical, or nearly so.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

Prosperity of Butte.—Zinc and Sulphuric Acid.—Oil and Gas.—Explosion at the North Butte.—Apex Litigation.

It is generally conceded that at no time in the history of Butte has there been more real mining or substantial progress than at present. There may have been more easy money for some during the Heinze days and the times of open gambling, but what I refer to is real prosperity, when profit is made by underground work and recovering metals from ore. Of course the profits are not so manifest in a company centre like Butte, as they would be in a district with many small operators; but the money is coming out of the ground just the same, and the local community prospers from the wages earned and supplies sold.

The copper mines are working, not to their capacity, but to the capacity of the smelters; the same may be said of the zinc mines. All could produce more ore, but the smelters are unable to treat a greater quantity. No new ore discoveries of importance have been made recently, but ample reserves were already developed to take full advantage of the high prices of copper and zinc.

The mines may be making no important discoveries, but the smelters have a more cheerful story. Improvements in concentrating and smelting practice are continually being made, resulting in greater recoveries, enabling the mines to deliver lower-grade and more refractory ores than formerly. Something seems to be in the air regarding zinc smelting. The Anaconda company's Washoe smelter, which was busying itself with phosphate investigations a few months ago, has dropped that for the present, and is devoting much time to experiments in zinc smelting. Results must be encouraging, as the company is now developing several of the old zinc properties at Butte that have long lain idle. If the Anaconda smelter succeeds in making commercial zinc from the iron-zinc ores which occur in most of the old silver mines of Butte, an extended life is assured for the district, as there are dozens of large veins now unworked, containing ore of this character. An announcement from the Anaconda company that it is ready to receive pyritiferous zinc ores for treatment would be glad tidings indeed for Montana, as there are many such deposits now lying idle. The Anaconda smelter has been making large profits from one unexpected source; because of the large consumption of acid in the manufacture of explosives for Europe the price of sulphuric acid has risen high, and part of the acid made at Anaconda is now shipped to other markets, although the original intent was to use it locally entirely.

During recent months there has been considerable intelligent drilling for oil and gas carried on in various parts of eastern and central Montana. Large gas wells have resulted near Havre, and it is expected that the gas will be put to commercial use. Domes and anticlines in Cretaceous rocks in other parts of the State have been drilled, but so far without success; an exception to this last statement may be the oil recently struck in a well south of Billings, near the Wyoming line. Drilling near Ryegate and Harlowtown seems to have been intelligently done, but results were disappointing. The wells are usually drilled through the upper Cretaceous, stopping in the fresh-water Kootenai formation of the lower Cretaceous or Comanchean. Drilling is now under way on another dome south of Two Dot in Meager county.

As has been mentioned in two recent issues of the Press, on October 19, 600 lb. of dynamite exploded at the surface station of the Granite Mountain shaft, of the North Butte company. This explosion resulted in the death of 16 men, and the injury of several others, and did some damage to the surface equipment at the shaft. This accident, the worst that has occurred in Butte for many years, if not the worst in the history of the place, is at present inexplicable, and will probably remain so, as all those who were near the scene at the time were killed. The powder in question was in a mine-car, waiting to be lowered and distributed to the powder magazines in the mine. It was the last of several cars of powder which had been sent down. As far as anyone knows, no one was standing near the powder at the time of the explosion, although there were a score of men within a radius of 50 ft. of it. Various suggestions have been offered to account for the explosion, all of which are within the range of possibility, although it is unlikely that the real cause will ever be known. It has been suggested that a burning cigar or cigarette end may have been carelessly dropped into the car; or that something heavy may have fallen or been thrown into the car; or that a high power bullet from some distant hunter's gun may have dropped on the powder; or that some ill intending fellow had arranged a mechanism to explode the powder; or that some imperfection in the powder itself caused the explosion. There seems to be no dependable foundation for any of these theories, and they had best be passed without further comment. In consequence of the accident the operation of the mine is temporarily at a standstill, because it so happened that nearly all the dead men were bosses in varying capacities about the mine. The accident does not seem to suggest any further precautions which might be made in the handling of powder. The powder certainly has to be lowered into the mine, and the present method of handling seems to be adequate and safe. One does not expect frozen powder in transit in a mine car to explode. In fact, most men who work about mines find it necessary to give powder rougher usage than it would have in being transported down the mine in boxes in mine-cars. It would seem that the accident must be regarded as one of those rare and unavoidable misfortunes, which all men must consider themselves subject to, who have to handle or be in the neighborbood of high explosives.

If Julius Caesar could have dropped into the Federal Court in Butte any day during the past three weeks, it is doubtful if anyone there could have explained to him satisfactorily, in a short time, the meaning of the gathering together of so many men of importance and fame in the mining industry. Of course, it would have been necessary to explain to him that they were gathered in two groups on opposite sides of the room for the purpose of emphasizing the fact that they were supposed to think differently upon important questions, which the Judge was being asked to decide. But if Caesar had been sat down beside the Judge (G. M. Bourquin) and made to get his idea of the controversy over the mysteries of apex litigation from the same sources, but without the preliminary experience in such matters that the Judge enjoyed, it is doubtful if he would have been able to make head or tail out of the controversy.

In fact the Judge had to protect himself by asking the litigants point blank, in the early stages of the trial, what the controversy was all about. He knew, of course, that orebodies worth many millions of dollars were the bone of con-

tention, but as to how each litigant proposed to lay claim to these orebodies, the Judge was offered no positive clew, at first. He, therefore, asked both sides to give him a brief and lucid statement, if possible, of the legal issues involved. "For," said he in effect, "if these questions to be decided are purely geological, you have selected the wrong man to decide them; I suggest that the geologists be instructed to go outside and settle their geological differences among themselves, but if legal questions are involved, let these be clearly segregated as far as possible from geological impedimenta, so that the Court may exercise his legal judgment unclouded by technical mystification."

The Judge further asked the litigants to confine their expert testimony to five witnesses on each side, if possible, thus to avoid useless reiteration of the same point on the assumption that the number of witnesses saying the same thing would increase its effectiveness.

Never before has there been a trial of this nature in Butte where so much, and such expensive, evidence has been offered. Besides a long and talented array of expert witnesses on each side, great numbers of carefully prepared plans, sections, sketches, and models have been offered in evidence. Altogether more than 250 exhibits were introduced.

Much interest is being shown in the proceedings, not only by those financially interested, but also by various members of the community at large. The expert testimony offers a rare treat to senior students in the State School of Mines here, and they have been interested spectators at many of the sessions. Mining men and lawyers fill that part of the courtroom set aside for visitors.

The expert testimony has furnished an up-to-date course in geology to the audience. Structural geology, chemical geology, rock genesis, ore genesis, etc., have all been considered by competent witnesses, and under the most favorable circumstances for the layman, in that every effort has been made to present facts in a non-technical manner for the benefit of the Judge.

An unusual phase of the trial deserving favorable comment is the excellence and promptness of the reporting of its proceedings. Two court stenographers alternated in short periods throughout the day in taking down what was said. After one had worked for, say, half-an-hour he was relieved by the other. The one so relieved hurried to a private room and dictated his notes to a dictaphone. The dictaphone records were promptly transcribed by expert stenographers, so that the full day's proceedings were typewritten and in available shape shortly after court adjourned each day. This system was of great assistance to the litigants, as well as to the newspapers desiring to report the proceedings as news.

On the whole, one could hardly call the trial a lively entertainment. Occasionally a clever sally or a bright rejoinder would come out, but the ordinary course of the testimony seemed monotonous to the outsider. Part of this was due to the necessity for exact descriptions and reference to survey-points in describing structure at specified places, but it was mostly due to the halting manner of speech of the careful witness. The glib talker who started his answers before his questioner had finished the question did not prosper on the witness-stand. The halting words of the witness who was trying to be exact and guarded in his testimony made hard work for the audience. In fact, a look of forced interest characterized the countenances of those inside the witness-rail and those outside as the day wore on. The Judge showed more sporting blood in that regard than anyone; apparently he was an attentive listener throughout the entire proceedings, interjecting pointed questions occasionally, and endeavoring to absorb everything that was said.

One is surprised to observe how seriously the Judge takes his responsibilities. As he himself had occasion to state, at one point in the trial, his decision will hardly be accepted as final. The case will be appealed to the higher courts, whichever way he decides, so that a less conscientious man might be inclined to humor himself by the realization that his opinion would not be accepted in any case.

The element of personal interest in the outcome of the trial was not as apparent on the Butte & Superior side as it was on that of the Elm Orlu. The president and the manager of the Butte & Superior were in attendance, naturally, but the real owners of the Elm Orlu were present in the flesh. Both W. A. Clark and W. A. Clark, Jr. attended nearly all the sessions of the trial, consulting and advising with their counsel and expert witnesses as the case progressed.

As is usual in such cases there proved to be a vast difference in the ability of the various experts to convey their thoughts definitely and clearly. For a man who is burdened with his own conceit, and an insufficient foundation to justify his self-esteem, a grilling on the witness-stand is excellent medicine. He finds arrayed against him clever lawyers and experts eager to disconfit him, to dissect his inaccuracies of thought and statement, and flaunt them before the Judge. Nevertheless the trial has been characterized by very little bitterness, or meanness of spirit. Considering the money involved it was rather remarkable that so few personalities were indulged in. Differences of opinion were plentiful enough. In fact, a disinterested observer could hardly believe both sides were trying to tell the truth, so diverse was their presentation of facts. This condition became so noticeable that the Judge finally essayed to see for himself and has agreed to go underground, in order to view certain disputed conditions with his own eyes.

There is no use beating about the bush in the matter; it cannot be gainsaid that the retained witness is prone to be biased in favor of the signature on his pay-check. The better of them will not bear false witness in the narrow sense of the word, but when it comes to fulfilling their oaths and telling "the whole truth," there is frequent room for suspicion. There is an undoubted tendency to put the loud pedal on points favorable to their clients and at least the soft pedal on points unfavorable. Would it not be better to have an independent expert advisor, one who did not care a rap for either side, but whose sole duty was to advise the Court fully and candidly? A case in point came up during this trial. A much mooted question throughout the proceedings was the significance of gouge in relation to the age of the vein. One witness would set his jaw and declare that the gouge showed antecedent mineralization. An opposing expert would declare with equal firmness that the gouge was there first, in fact, the gouge was what controlled the direction of the circulating solutions. The Judge was apparently left pretty much in the air after all this. The facts were but partly made clear to him, that gouges could be pre-mineral, post-mineral, or formed during mineralization; that a given gouge might have been formed under all these conditions, and that in many cases the evidence was not conclusive as to when it was formed, and that it was therefore of little real value as evidence if the experts could interpret it so differently.

The experts at the trial were, as some one expressed it, the "usual bunch," with one or two novices. Western apex-suits are getting to be regarded as unimportant if Finch, Winchell, Wiley, Burch, and Weed are not on hand.

GOLDFIELD, NEVADA

New Producers.—Goldfield Consolidated, Jumbo Extension, Atlanta, Kewanas, Sandstorm-Kendall, Simmerone, Merger, Great Bend, and Other Mines.

The number of producing mines in the Goldfield district has lately been augmented by three, namely, the Kewanas, Atlanta, and Simmerone. The Atlanta has shipped some medium-grade ore in the past, and the Simmerone yielded some very rich ore from surface workings in the early days of the district, but the Kewanas is now starting production for the first time, and from the quantity of medium-grade ore opened, and the similarity of geological conditions to those in the

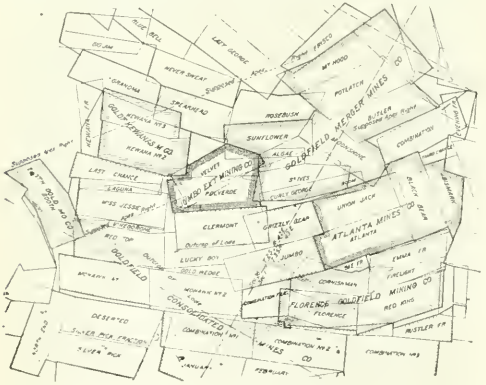
Jumbo Extension ground, those in authority believe a substantial output is assured. There is reason to believe that the time is fast approaching when large quantities of the lower grade, copper-bearing ore of the district will be treated here profitably by flotation.

The estimated production of the Goldfield Consolidated Mines Co. in October is as follows:

Ore mined, tons	36,500
Gross extraction	$256,000
Operating expense	155,000
Net realization	101,000

The tonnage mined and treated by the Goldfield Consolidated in October, 36,500, is the largest for any single month in the history of the company's operations. The principal production is from the Mohawk, Red Top-Laguna, Combination and Clermont mines. The large radial cableway, the installation of which was completed several months ago, has not been used, as it has not been necessary to draw on the tailing-pond to supplement the supply of ore from the mines.

Deeper levels of the Jumbo Extension mine are opening quantities of high-grade ore, both in the shale-contact zone



PRINCIPAL PROPERTIES AT GOLDFIELD, NEVADA.

and in the fissure that extends within the shale. Drift No. 530, the farthest point to the southeast at which the contact-zone has been penetrated, has continued for 170 ft. in ore of uniformly high grade, the daily assay-sheets indicating averages of from $50 to $200 per ton across 4 to 8 ft. Raises from the 1017 and 975-ft. levels have connected with this drift, improving ventilation and facilitating extraction. Two stopes have been opened on the contact ore, at points 100 and 200 ft. above the rich No. 524 drift, or 880-ft. level, on the flat dip of the shale. The first stope, No. 541, is showing ore of excellent grade, faces 4 to 6 ft. wide lately assaying $60 to $350. Production is maintained at the usual rate of two 45-ton cars daily, with occasional additions to this amount. The Velvet or No. 2 shaft is progressing rapidly, and should be completed early in January to the 1017-ft. level, with connections made at the 780, 860, and 1017-ft. levels. Production will then be practically doubled.

Conditions in the Atlanta mine are reported by the manager, A. I. D'Arcy, to have shown decided improvement of late, particularly on the 1580 and 1620-ft. levels, where ore of shipping grade, has been exposed in considerable quantity. A drift on the 1580-ft. level is showing 5 ft. of ore assaying $28 per ton gold, in addition to from 4 to 6½% copper, and a little silver. Stoping has begun in two places and shipments will be made regularly. On all four levels large bodies of lower grade, copper-bearing ore are exposed.

Stoping is now in progress in the Kewanas, at a depth of 840 ft., where a drift has followed the ore-shoot for 160 ft. For about 60 ft. of this distance the drift shows 3 to 5 ft. of ore that can be shipped profitably, averaging around $40 per ton, and containing a small amount of copper. The east cross-cut from this drift exposed the hanging wall, 40 ft. distant, and cut a number of seams of pay ore varying in width from 9 to 30 in. Near the hanging wall a winze is being sunk, timbered to 20 ft., and provided with platforms. The foot-wall has not been exposed. The new winze is being sunk to reach the shale-contact zone, and it is apparent that this will be reached shortly.

At a depth of 700 ft. in the Sandstorm-Kendall, the east cross-cut from the incline winze has progressed over 100 ft., and has not yet exposed the foot-wall of the lode, which is thought to be within 50 ft. of the winze. Seams of medium-grade ore have been cut in this work and a raise will be driven to determine the degree to which the vein has flattened. The winze, sunk at a dip of 70°, left vein matter and has been in andesite from a point 60 ft. below the 500-ft. level.

The orebody found in the Simmerone, in a raise 35 ft. above the 100-ft. level, promises to yield some ore of excellent grade. The raise was continued 14 ft. on the ore, and from here a winze, on a flat incline, is following it down toward the drift on the 100-ft. level, where it will be sought by drifts now being advanced at this depth. H. C. Cutler, consulting engineer for the company, sampled the ore sacked from a shoot averaging 2 ft. wide, and obtained an average of $117 per ton. The foot-wall of this rich seam, for a width of 3 ft., is said to assay $42 per ton when screened. The discovery was made in territory leased for a term of three years from the Blue Bull Mining Company.

Results of work by the Merger Mines Co. have been significant in determining the position and course of the shale-contact zone of silicification south and south-east of the Jumbo Extension ore-channel. The north-east cross-cut from the east contact-drift on the 1175-ft. level has advanced over 200 ft. and passed out of the shale, through a wide quartz zone, containing much iron and some copper, and is now in latite. The manager, Willis Lawrence, explains that his plan is to continue this cross-cut to the contact-zone at the other side of the valley or depression in the shale's surface, farther east and presumably in the Sunflower claim, after which drifts and raises will be driven to explore the two quartz zones. Connection for air will later be made with the Jumbo Extension workings on the 1017-ft. level of the latter, and the workings will be connected with the main or St. Ives shaft of the Merger.

The Great Bend company has completed repairs to shaft timbers near the 400-ft. or bottom level, and a cross-cut has been driven south from the sump, to afford additional sump capacity, also to serve later for development in this direction. Driving is in progress to the east, following the main branch of the lode, for a point 100 ft. distant, below a winze from the 250-ft. level where rich ore was found by early lessees. The surface plant is a duplicate of that installed at the Velvet shaft of the Jumbo Extension and a compressor and jack-hammer drills, with driving columns, have been installed lately.

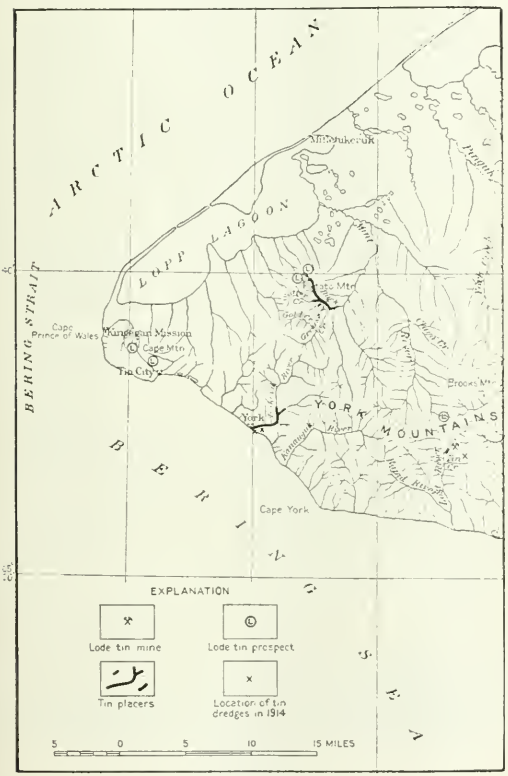
A cross-cut east from the station on the 600-ft. level of the Silver Pick Consolidated has penetrated the main lode and is in quartz of good appearance, yielding low assays in gold. At the west, on the 500-ft. level, drifts are exploring the Phelan vein and show some good mill ore.——The 250-ft. main shaft of the Spearhead Gold Mining Co. is being unwatered and provision has been made for sinking to the shale-contact, an estimated depth of 1000 ft.——Lessees on the Diamondfield Black Butte property have exposed high-grade ore at a depth of 110 ft., and the company is preparing to install a compressor for the use of the lessees.——Work will be in progress shortly on the Vernal, Oro, Grandma, Kewanas Extension, and several other properties here, in addition to the 17 companies now operating and whose stocks are listed.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Since 1902 the output of metallic tin in Alaska amounts to 526 tons valued at $380,006, according to Henry M. Eakin in 'Tin Mining in Alaska,' Bulletin 622-B of the U. S. Geological Survey, of 14 pages and two maps. Most of the black tin was extracted in the York district of Seward Peninsula, north and



MAP OF YORK TIN REGION, SEWARD PENINSULA.

west of Nome. Some tin has been found northeast of Fairbanks. Since 1911 one dredge has worked on Buck creek, while two boats were built on the Anikovik river in 1914 to recover gold and tin together. Lode tin was found at Cape mountain in 1902. A. J. Collier and F. L. Hess of the Survey discovered a lode on Lost river in 1913, and extensive work is underway there. A mill is operated. About 40 men are employed in the tin industry.

Cordova

On account of shortage of vessels copper ore from the Bonanza and Jumbo mines of the Kennecott company is accumulating at Cordova. At present there is 3500 tons averaging 70% metal, and 14 cars of other material, the whole worth $968,000.

In order to cope with the winter traffic the Copper River & Northwestern railroad has ordered a new rotary snow plow and three oil-burning Mikado type engines from the American Locomotive Works, also 15 box-cars of 50-ton capacity from the Seattle Car & Foundry Company.

During the season the Valdez Creek Placer Mines, operating near Broad Pass, purchased 60 acres of dumping ground, doubling the capacity of the hydraulic plant. In No. 2 pit 15 and 18-in. pipe, and two 7-in. nozzles are being installed; also 1400 ft. of Bouery steel riffles in the 5-ft. flume. Other machinery is to be erected. Hydraulicking for the season was completed on October 10, and will resume in May, 1916.

Juneau

September returns of the mines on Douglas island were as follows:

Results.	Alaska Mexican	Alaska Treadwell	Alaska United
Development, feet	184	503	1,096
Stock of broken ore, tons	—10,172	+7,594	—8,932
Stamps dropping	120	540	270
Ore crushed, tons	18,690	80,472	42,994
Gold from all sources	$26,543	$150,345	$69,498
Yield per ton	$1.42	$1.87	$1.61
Operating expenses	22,149	88,252	52,207
Construction charges	1,786	7,929	12,641
Profit	$2,342	$52,661	$3,955

On October 24 the new 30 stamps at the Ready Bullion mill of the Alaska United commenced work; this makes a total of 300 stamps for that mine. It is motor driven throughout. Four double-deck Deister tables are used. The drainage-ditch above the open-cut at Treadwell to prevent water going into the mine, is finished. It is over ½ mile long, and is in rock for some distance.

Valdez

A raise from the 350-ft. level of the Granite mine on Hobo bay has cut the vein, where it is high grade. The property is equipped with two crushers, rolls, 10 heavy stamps, a 7-ft. Lane mill, three tables, etc., also two 80 and one 180-hp. oil engines, one 150-hp. generator, motor-driven compressor, etc. R. W. Millard is in charge.

ARIZONA

Cochise County

The report of the Wolverine & Arizona Mining Co. for the year ended September 30 shows the following: 7610 tons of 6.21% copper ore was shipped to the Copper Queen smelter at Douglas, returning $130,370 net, or $17.13 per ton. Cash on hand amounts to $155,974. Work during the past year was largely confined to exploiting a sulphide orebody, situated in the eastern end of the Warren claim, high up in the mountain above the Higgins adit, which serves as a main entrance for the workings. In December of 1914 an initial dividend of 20c. per share was paid.

During the bombardment of Agua Prieta, just across the border in Mexico, people in Douglas were in danger from the shooting. Schools were closed, and it was possible that the Calumet & Arizona and Copper Queen smelters would be affected.

GILA COUNTY

At Chilito, seven mines north of Hayden, where is the A. S. & R. Co. smelter, a rush has set in for a new gold discovery.

At the Old Dominion, at Globe, the concentrator is treating 700 tons of ore daily, 100 tons of which is from the Arizona Commercial. The mine is producing between 900 and 1000 tons, mostly from No. 12, 14, and 16 levels east and west. The daily output of water is under 6,000,000 gal. The pump motors at No. 18 station are being overhauled. The smelter produced 2,700,000 lb. of copper in October.

Half of the Inspiration mill is at work. Machinery for the remaining nine sections is arriving. The coarse-crushing plant is working well, and both main shafts are in commission. An Otis elevator is used for lowering or raising men in the west shaft. The miners' change-house is making good progress.

According to deputy State mine inspector John Harper, safety work in the Globe-Miami district is giving good results.

GREENLEE COUNTY

On November 4 a parade of over 2000 miners was held at Morenci. At Clifton over 2000 strikers were addressed by J. T. Walker, president of the Illinois Federation of Labor. He urged firmness, without violence. Press news is being censored by the Western Federation.

On November 5 No. 2 and 3 units of the Arizona Copper Co.'s concentrating-plant, the new conveyor-plant, and ore-bins at Clifton were destroyed by fire. Further damage was stopped by dynamiting buildings. The loss is very heavy. The outbreak was mysterious, but officials are non-commital.

MOHAVE COUNTY

The Grand Gulch, Bronzell, and Copper Mountain mines are shipping over 200 tons of high-grade copper ore per month to smelters in Utah.

The Santa Fe railroad is to construct a line from Topoc to Oatman. It will follow the route of the old Mohave and Milltown line, a narrow-gauge logging road abandoned years ago.

Oatman has been visited by J. Parke Channing, who is reported to have said after going through the underground workings of the United Eastern, and an inspection of its properties in the southern part of the district:

"I was agreeably surprised at the showing of the United Eastern mine, although I was prepared to see a big amount. The orebody developed in the property is big and strong, and I am told carries unusual gold-content. The property is entitled to rank among the big gold mines of the country. One cannot obtain much of an idea of such an extensive mining area in a brief 24 hours. Structurally, however, it is obvious that the veins or lodes are of unusual breadth and strength. The camp undoubtedly has great promise, and I shall be surprised if there are not numerous big mines developed here. The region pleases me very much."

The United Western company has cut lode formation at 500 ft., which shows gold on panning.

Oatman is growing at the rate of 50 people daily.

CALIFORNIA

AMADOR COUNTY

At the Allen copper mine, near Ione, three shifts are sinking the shaft, in which is a large flow of water.

ELDORADO COUNTY

Three miles east of Placerville is the Rising Hope gravel mine managed by G. W. Englehardt. During the past five years over 10,000 ft. of work has been done, and the mine is now producing gravel worth $2.50 per car of 1600 lb. The barrel type of mill treats 6 tons per hour. C. M. Hensen is superintendent.

Gravel and quartz mines around Placerville are giving good results lately.——Burr Evans has secured a lease on the Consumnes quartz claims near Omo, south-east of Placerville.——Los Angeles people have leased the old Stillwagon quartz mine on the Consumnes river. It is opened by an 800-ft. adit, and is equipped with stamp-mill and electric power-plant.——At the Judson 'pocket' mine near Diamond Springs three shifts are working. A pumping-plant has been installed.

NEVADA COUNTY

Good progress is reported from the Polar Star mine, and more men are to be employed. The electric hoist and pumps are nearly ready.——The new 10-stamp mill at the Columbia, near Washington, is crushing 50 tons per day.

PLACER COUNTY

The Big Oak mine near Colfax has been unwatered and examined, and the optionees are to commence development. The 240-ft. shaft is to be sunk to 300 ft. A mill is contemplated. F. H. Hubble, J. Toman, and R. C. Chapman of Colfax hold the option.

SAN BERNARDINO COUNTY

(Special Correspondence.)—New developments at Atolia during the past week were the finding of two new tungsten veins. One of these was cut by driving on 60-ft. level of the Skylark claim, an easterly extension of the Atolia company's ground on a lease worked by Brock & Lypp. The vein is said to be three feet wide, half of which will average 60% WO_3. The other discovery was in a shaft several hundred feet north at bed-rock, by P. J. Osdick, owner of the Mascot claim.

Fully three miles from the Atolia area, on the Randsburg road, along the route of the new pipe-line, another important find of scheelite ore was made on October 24. The vein is about 4 to 6 in. wide, and exceptionally high-grade. Bob Tate of Randsburg has acquired a lease on the property, and begun extracting ore from the surface. This latest discovery enlarges the tungsten belt several miles, and establishes an area of 15 sq. miles where scheelite veins are known to be producing high-grade material.

A fire on October 26 destroyed a bunk-room and store-house adjoining the Atolia mill; the loss was about $250. Lack of water and great excitement were the principal characteristics. The mill was in danger for a time.

About 40 new claims were staked by prospectors and promoters between Atolia and Cuddaback lake this week. Several auto parties have been camped in that locality, and some have pitched camp and begun sinking holes to bed-rock.

Owners of the Scheelite group are expecting a Keystone drill which has been ordered from the East. A 90-day contract on lease and option contains provision for constant drilling on the property until January 1, 1916.

Atolia, October 25.

SIERRA COUNTY

Stamps and concentrators are to be ordered by A. W. Copps for the Irelan mine near Alleghany, controlled by the Durston Gold Mining Co. Good ore has recently been opened. The mine is an old producer.

At the Excelsior mine near Forest Hill the second lot of stamps has been erected. Six are now crushing 100 tons per day. Another unit is to be installed.

TRINITY COUNTY

At the Bonanza King there are 30 miners employed. No. 4 adit has cut a rich shoot. The mill is being moved to the mouth of this adit.

TUOLUMNE COUNTY

Control of the Dutch-Sweeney Mining Co. has been secured by W. J. Loring for Bewick, Moreing & Co. of London. The mining company holds options to purchase the Dutch and Sweeney properties near Sonora from J. F. Thompson and C. H. Segerstrom, and the App from the Central Land & Trust Co. of Fresno.

YUBA COUNTY

Another large dredge, No. 15, is to be constructed by the Yuba Construction Co. at Marysville, for the Yuba Consolidated Goldfields Co.

COLORADO

Boulder County

As long as tungsten ore is at $30 per unit the Primos and Wolf-Tongue companies will pay shovelers $3.60, laborers, $4.20, and the $4 and $5 men $4.80 and $6 per day. These are increases of 20%. The Primos company is offering good terms to lessees on its tungsten properties, these being 15% royalty and the market price for ore. Some owners demand 25% and only pay $15 per unit.

A rich tungsten and gold area is reported by A. Graves of Denver to have been discovered in this county, but the situation has not been revealed. Specimens of the ore were shown at Denver.

The Nederland tungsten region is very busy, and the town is full of new people coming and going. Accommodation is scarce. For miles the country has been trenched by prospectors. While many are making money, others are not.

Clear Creek County

(Special Correspondence.)—The Sun and Moon mine on Seaton mountain, has been taken over by the Val Tilborg M. & L. Co. Development is being done through the Newhouse adit, and 2 ft. of smelting ore is exposed, assaying $45 per ton gold, silver, and lead. Nels Holme is manager.

The Gunnell mine on Quartz hill, operated by a local pool of mining men, is yielding ore that is worth $400 per ton. In sinking a winze from the drift off the Newhouse adit a production of $100 per foot is made. Rens C. Schirmer is manager.

Klein & Co., Leasing on the East Lake through the Big Five adit, are shipping on an average of three carloads of $30 ore each week.

Swan, Smith & Co., operating under lease on the Gem, have a large shoot yielding around $40 per ton. The ore vein has a width of three feet.

On the 1200-ft. level of the Old Town, a body 4 ft. wide is exposed that assays $200 per ton in gold. George R. Kimball is manager.

The property of the Almaden Mines Co. was sold last week at sheriff's sale to satisfy a judgment in the sum of $27,596 obtained out of the district court by J. A. Greenfield of Bellaire, O. and George Neill of Topeka, Kansas, the bondholders. The holdings were purchased by the two men in question, who announce that a campaign of development will at once be commenced.

The Mary L. Co., controlling the Mary mine on Bellevue mountain, is being developed. Operations are conducted through the Big Five adit.

Idaho Springs, November 2.

Dolores County

On November 1 the Wellington Mines Co. paid dividend No. 9, amounting to $200,000. From December 1, 1914, to October 1, 1915, sales realized $438,336 for zinc, and $39,681 for lead concentrates, a total of $478,017. The profit was $323,630. Three dividends absorbed $300,000.

Gilpin County

The U. P. R. mill has been treating ore from the Gilpin-Orion mine on Gregory hill; it returned up to 10.11 oz. gold, 16.5 oz. silver, and 8.8% copper.

Lake County (Leadville)

A new station pump is to be installed at the Down Town Penrose shaft. It will be a Providence Engineering Works machine of 2000-gal. capacity per minute, driven at 1800 r.p.m. by a General Electric 650-hp. motor. The machinery will work at 900 ft. depth. Water is now down below 655 feet.

The proper course for extending the Yak tunnel into the Aladdin claims is being investigated.

Lessees in the district are doing well, their work being of great value to the community.

Ouray County

The Mountain King company has opened a body of lead-zinc ore from 4 to 5 ft. wide; also a large flow of water.——High-grade gold-silver ore has been opened in the Ores-Metals property.——In September the Camp Bird treated 2655 tons of ore for a profit of $55,200.

Summit County

During the August quarter the Tonopah Placer Co.'s net earnings were $114,000.

Teller County (Cripple Creek)

The estimated output of the district in October is as follows:

Mills.	Tons.	Average value.	Total value.
Smelters, Denver and Pueblo	4,025	$55.00	$221,375
Portland, Colorado Springs	11,000	20.00	220,000
Portland, Cripple Creek	19,100	2.97	56,727
Portland, Victor	12,400	2.36	28,264
Golden Cycle, Colorado City	43,450	17.00	738,650
Gaylord	1,400	3.00	4,200
Caley	800	4.00	3,200
Total	92,175	$13.80	$1,272,416

The tonnage is the largest recorded.

October dividends were as follows: Portland, $90,000; Vindicator, $45,000; and Golden Cycle, $30,000, while the Cresson and Strong also made distributions.

The drainage-tunnel advanced 305 ft. in October, and the face is 900 ft. from a point under the Elkton shaft.

On No. 11 level of the Mary McKinney 8 to 12 in. of 6-oz ore has been opened; on No. 9 level there is 8 to 10 in. of 5-oz. ore.

On No. 10 level of the C. O. D. mine telluride ore has been cut.

The Isabella property, on company and lessees' account, yielded 1850 tons of $20 ore in October; November may be larger. The company has resumed work at the bottom or No. 15 level of the Lee shaft.

On the evening of November 1 the Gaylord mill was burned to the ground. The fire resulted from an explosion of gasoline, which took place while bullion was being melted.

From the open-cut of the Shoo Fly claim on Womack hill, Stratton estate, Hickman & Co. received $91.40 per ton for 200 tons.

Armed guards accompanied two cars of ore worth $100,000 from the Cresson mine to the Golden Cycle mill at Colorado Springs.

The Colburn mill is treating 60 tons of ore per day from the Ajax mine. Custom and lessees' ore is to be treated.

IDAHO

Shoshone County (Coeur d'Alene)

The possibilities of the Pine Creek district are becoming better understood as the area is investigated. The ores contain antimony, lead, silver, and zinc. After leaving Wallace the first mine on the Pine Creek side of the summit is the Sidney. It has been developed by adits, and contains a good deal of lead-zinc ore.——A half-mile distant is the Little Pittsburg. Zinc ore has been opened.——The Highland-Surprise employs 30 men. A new mill is ready for work.——Near the forks of Stewart and Pine creeks is the Antimony-Silver mine. Adit No. 1 shows 2 ft. of high-grade antimony ore, while No. 2 has 5 ft. The dumps contain 5 tons of high, and 200 tons of second-grade ores.——In the Constitution mine is a zinc ore-shoot 500 ft. long; a lead vein runs parallel to this. All of the above properties are supplied with electric power, and have fair transport arrangements.

At 900 ft. in the Marsh mine at Burke the drift from the cross-cut has cut 18 in. of silver-lead shipping ore. The shaft is soon to be sunk to 1200 feet.

A circular reports that during the three months ended September 30 the Caledonia company, near Kellogg, produced

1560 tons of shipping ore and 2389 tons of concentrate, containing 306,080 lb. lead, 319,500 oz. silver, and 182,783 lb. copper, worth a total of $318,248. The net profit was $193,294, and $234,450 was paid in dividends. The excess payments were drawn from the surplus. Twenty-eight miners were employed one shift for six days per week.

An apex suit is to be commenced on November 16 between the Alameda Mining Co. and the Success Mining Co., the former alleging wrongful extraction of $30,000 of ore.

Mullan men have taken a bond on the Elk company's ground near the Morning and Hunter mines, on Mill creek, for $50,000. The Independence company is the largest operator in this area.

No definite situation has been announced for the Bunker Hill & Sullivan smelter, but it is expected to be near Kellogg. The company is investigating freight rates on smelter products, which may decide the place for the plant.

MICHIGAN

The Copper Country

Copper production in October is estimated as follows by *The Mining Gazette* of Houghton:

Mine.	Pounds.	Mine.	Pounds.
Calumet & Hecla	6,700,000	Superior	323,000
Copper Range	4,500,000	Franklin, Jr.	364,500
Quincy	2,220,000	South Lake	18,500
Tamarack	588,000	Isle Royale	978,000
Osceola	1,638,000	Hancock	190,000
Ahmeek	2,127,000	Victoria	270,000
Wolverine	580,000	Winona	238,000
Mohawk	1,404,000	White Pine	726,000
Centennial	220,000	LaSalle	182,500
Allouez	865,000	Houghton	52,000
Mass	552,000	Lake	187,000

Another furnace is to be blown-in at the Calumet & Hecla Dollar Bay plant in a few days. During one 8-hr. shift last week at the C. & H. No. 4 and 5 conglomerate branch there was hoisted 48 and 51 cars of ore respectively. These hold 7.5 tons each, some coming from a depth of 6000 ft. Contractors on tramming and mining earned $4 and $6 per shift respectively.

Shipments of copper through Portage lake in October amounted to 14,726 tons.

MISSOURI

Jasper County

In *Technical Paper* 105 of the U. S. Bureau of Mines, A. J. Lanza and Edwin Higgins discuss pulmonary diseases among miners in the Joplin district, and its relation to rock dust in the mines. In the 47 pages a variety of interesting subjects are discussed, and all mining men in the region should secure a copy. According to C. M. Harlan of Carterville, a State deputy mine inspector, the sanitary conditions of the mines are 50% better than a year ago. He acknowledged the help of the Bureau.

The annual drilling contest of the Hercules Powder Co. was held at Joplin on November 7, and great interest was shown. Results in past years are 31 13/16, 34 9/16, 35 13/16, 36 3/4, and 37 1/2 inches.

MONTANA

Lewis and Clark County

The Helena Mining Bureau has secured a bond on the Yellow Boy mine in the Unionville district. A wide vein of fair value has been developed, and ore treatment may be commenced in December.

The Head property of 80 acres, in the Scratch Gravel district, has been purchased by T. B. Miller for Helena and Butte interests for $42,000. A fair amount of development has been done, and a great deal is to be started. Six cars of gold-silver ore recently netted $22,000.

Silverbow County

Almost in the centre of Butte is the Anaconda company's Emma zinc mine, which is now being developed after 12 years' shut-down. It has been fully equipped, and is in charge of J. Brennan, well known at Butte. Unwatering is in progress, the water being down to 300 ft. Good ore is expected when mining commences. The company is also unwatering the Nettie mine west of Butte. The shaft is 560 ft. deep, it has been re-timbered to 400 ft., at which depth pumps are working.

In the Elm Orlu-Butte & Superior suit the defense concluded argument on November 4. Judge Bourquin examined the area in dispute on the 8th and 9th, accompanied by an engineer from both sides.

At the Butte & London three shifts are shaft-sinking at the rate of 100 ft. per month in granite. The bottom is at 1100 feet.

The Butte-Ballaklava is shipping at the rate of 7000 tons of 4% ore per month, mostly from 1300 to 1600-ft. levels. A winze is down 90 ft. below the 1600-ft. level. Eighty men are employed. Profits are satisfactory.

NEVADA

Churchill County

At the end of the quarter ended September 30 the Nevada Hills company had $33,158 cash on hand, and net resources of $277,478. Ore reserves are small and profits irregular.

Humboldt County

During October the Seven Troughs Coalition mine yielded gold worth $60,000; November is expected to be still higher. Stopes at No. 13 level show one to four feet of $300 to $1000 ore. The shoot so far is 100 ft. long. The winze below 1400 ft. is down 100 ft. Generally the property is in excellent condition. An extra dividend is expected.

The Rochester Mines Co.'s output in October was $40,000, a decrease on account of several delays. On the 415-ft. level from No. 1 winze in block 2 of the Crown Point the vein is 15 ft. wide, some ore showing gold. The average across is from $20 to $25 per ton. The Nevada Short Line, from Nenzel to Rochester, earned $3733 in October, each month shows an increase. Starting at $1 per ton for ore assaying $20, the freight rate increases 50c. on each $10 in valne. New cars are to be ordered.

Lincoln County

Pioche is busy; companies are shipping more ore than before, there is more leasing than before. Developments at the Prince, Home Run, Atlas, Gold Chief, and others are considered good.

Lyon County

The Nevada-Douglas company, in order to take advantage of the present copper market, is shipping each week several carloads of ore to the Salt Lake smelters. This is being taken from the large high-grade deposit recently uncovered in the Ludwig portion of the mine, and will yield over $1500 per car net, after deducting the cost of mining, transportation, and treatment.

On the north-east slope of Yerington mountain, 9 miles north-west of Schurz and 20 miles from Yerington, is the Yerington Mountain Copper Co.'s property. It is said to be of great promise. A 500-ft. shaft, and three adits, etc., have opened good ore. Further development is under way.

Nye County

Companies and lessees at Tonopah last week produced 10,343 tons of ore worth $212,134.

The Extension shipped bullion and concentrate worth a total of $80,000. September profits were $52,000. Interest underground centres at the 1350-ft. level. The new 20-drill compressor is nearly installed, likewise additions in the mill.

The new shoot at 1200 ft. in the Halifax is attracting more attention than any other development in the district. It will

prove the extension of the Tonopah vein system 1750 ft. beyond the Belmont property.

The apex suit of the Tonopah Victor *v.* the Tonopah Cash Boy company has been settled.

The West End mill treated 1173 tons of ore last week; 904 from the West End mine, 54 from the North Star, 50 from the Halifax, and 165 from lessees at various properties.

Lessees at the Montana are shipping $28 to $35 ore.

SOUTH DAKOTA

Lawrence County

To treat its low-grade tungsten ore, the Wasp No. 2 company is to build a 15 to 30-ton concentrating plant. The high-grade material is shipped direct. On account of the greater depth of mining the gold ore (open-cut work), that assaying less than $2.50 per ton cannot be profitably treated. The mill is only treating 150 tons per day, and 40 men have been paid-off.

Pennington County

The tungsten area near Hill City is extending east, where good prospects are reported.

UTAH

Boxelder County

Early in March there were three men at Promontory Point, 30 miles west of Ogden; now there are 200 miners at work and a busy town is growing. The peninsula, jutting into Great Salt Lake, is 42 miles long and 8 miles wide. Various metals are mined in the mineralized belt, including zinc from the Lakeview company.

Juab County

Tintic mines shipped 116 cars of product last week. Good progress is made by the Tintic Milling Co. and G. H. Dern expects the plant complete on January 1.——Lessees in the Chief Consolidated are extracting rich zinc ore.——Lessees at the Yankee Consolidated are sending occasional lots of 42% zinc ore. The company is preparing another shipment of ore from the new development, assaying 200 oz. silver, 10% lead, and up to $8 gold per ton.

'Process of Mineralization and Enrichment in the Tintic Mining District,' is the title of a paper in *Economic Geology* for April-May by Waldemar Lindgren. From 1869 to the end of 1914 the estimated output of silver, gold, lead, copper, and zinc is $154,166,221. Small quantities of arsenic and bismuth are also recovered. The ore deposits are contained in the monzonite and in the limestones and dolomites north of the monzonite area. In the monzonite there is a system of many veins trending north or northeast, which, however, have yielded only a small part of the production of the district. The deposits in the limestone area are replacement veins generally following north and south fractures, but which also in part follow northeasterly cross breaks or the regular bedding planes of the limestone. The intersection of the cross breaks which dip north-west with the north-south fractures produces a tendency of the shoots to pitch northward. Besides, in a broader way, the shoots in the northern part of the limestone area are found at lower levels than those farther south. The shoots form lenticular masses or a series of detached, pod-like bodies, or pipes, separated by long stretches of lean or barren ground.

Explorations in ore below water-level are so far confined to the Gemini mine, where a winze was sunk from 1650 to 1900 ft., water now standing at 1650 ft. An irregular shoot was followed from 1300 to 1900 ft. Ore found just above and below water-level differed remarkably. The sulphide ore found in this shoot is very rich in silver. It occurs in a breccia of dark jasperoid and dolomite. Much of the jasperoid is similar to the ordinary normal sulphide ore, and contains finely disseminated galena, pyrite, and zinc-blende.

The following conclusions were arrived at from Mr. Lindgren's investigation: (1) The jasperoids along the deposits were formed by the replacement of limestones and dolomites by colloidal silica, which later crystallized to chalcedony and quartz. This is the first depositional phase. (2) The contraction and crushing of the silica caused this material to become brecciated, and the silica of the second phase was deposited in open spaces as colloid silica, which later crystallized to quartz. (3) The development of crystalline barite, galena, and other sulphides accompanied both these phases. (4) During the deep oxidation of the deposits secondary copper sulphides (chalcocite and covellite) were formed at all levels, together with oxy-salts. (5) The gold was concentrated in places at all levels in the copper mines by secondary processes, involving the development of free chlorine and gold chloride. (6) The rich silver sulphides such as argentite and proustite are probably all secondary and were formed during the oxidation.

PRINCIPAL PROPERTIES IN THE TINTIC DISTRICT.

(7) Few data are available to determine the character of the ore below the water-level. But the only shoot opened around the water-level shows a remarkable galena ore, rich in silver, pearcite, spherulitic zinc-blende and marcasite, which clearly was deposited later than other ores in the mine. It may possibly have been formed by descending waters at a time when the water-level stood somewhat higher than at present. And (8) partial oxidation has proceeded in this rich shoot to a depth of 250 ft. below the present water-level.

Salt Lake County

Transactions at the Salt Lake City Stock Exchange during October totaled 1,055,746 shares, valued at $240,027. Developments in the American Fork and Big and Little Cottonwood districts, an area of 5 by 10 miles, continue to be of importance; ore production is increasing. The Alta Tunnel & Transportation Co.'s adit is in 1615 ft. in promising formation.

In the last Bulletin of the A. I. M. E. the disseminated copper ores of Bingham canyon are discussed by J. J. Beeson of Stanford University, California. The paper covers 46 pages, including nine plates.

The Ohio Copper mill is treating about 2000 tons of ore daily, with a monthly output of 600,000 lb. The property is leased to the General Exploration Co., which pays at present a monthly royalty of $15,000. The royalty is based on the current price of copper.

Summit County

Striking miners at the Silver King Coalition are returning to work, although the question of insurance has not been agreed upon yet.

Tooele County

In the Mercur district the M. & P. Gold Mining & Milling Co. is enlarging the filtering capacity of the cyanide-plant. About 125 tons of low-grade ore is to be treated daily. Arthur Murphy is in charge.

WASHINGTON

Kittitas County

Seattle people have formed the Millvick Milling & Smelting Co. to operate a property 35 miles from Roslyn, from which rich ore is to be shipped. Reduction works are contemplated. W. A. Burr is in charge.

The coalfields of this county are the subject of Bulletin No. 9 of the Washington Geological Survey, by Edwin J. Saunders. With illustrations, plans, and maps it covers 204 pages. The area lies at an altitude of from 2000 to 4500 ft. In 1913 the output of coal was 1,334,155 tons, out of a total of the State of 3,877,891 tons averaging $2.38 per ton. The Rosyln district was recently represented at the Panama-Pacific Exposition by a mine-rescue team.

Stevens County

According to V. W. Brasch, mining properties in the Cedar Canyon district in the southern part of this county are being actively worked, more so than during the gold rush years ago.

Spokane County

During October, mining companies in which Spokane capital is interested, distributed $1,344,156 in dividends, making $7,706,790 for the year and $71,023,069 to date from mines in British Columbia, Idaho, Montana, and Washington.

According to J. P. Graves, in a talk before the Spokane Chamber of Commerce, that city of over 100,000 people would have remained an agricultural centre of 25,000 had it not been for its mining interests in the contiguous territory. Larger growth is predicted.

CANADA

British Columbia

September profits of the Standard Silver-Lead company at Silverton were $88,057. At the end of the month the surplus was $224,779.

At 900 ft. in the Payne mine at Sandon two feet of high-grade lead-silver-zinc ore has been cut. This mine is an old producer.

Ontario

On December 1 the Dome Mines company will pay its second dividend of 5%, equal to $200,000.

At the Lawson claim of the La Rose company, 30 men are engaged in extracting 'plate' silver from near the surface. In the mine, exploration is under way from the new shaft at 350 ft. depth. Old pillars and dumps continue to supply a fair quantity of ore.

MEXICO

Sonora

One ton of scheelite arrived at Douglas last week from the Esperanza mine, in the Lampazos district; it is worth $38 per unit. The shipment was rushed through Villa territory on burros. The mine is owned by J. S. Douglas and others. According to superintendent, G. Burkart, a mill and power-plant will be erected when the country is quiet, where at present no properties are working except El Tigre, and food is almost unobtainable.

It is said that Villa demanded $25,000 each from the Greene-Cananea, Moctezuma, and Tigre companies, otherwise he would destroy their plants. The first named paid $20,000 in silver.

PERSONAL

H. A. Guess is in Chile.

Richard A. Parker is at Butte.

J. V. N. Dorr is in San Francisco.

Arthur W. Jenks is in British Columbia.

Llewellyn E. Humphreys is at Oatman.

Thos. H. Leggett is here from New York.

H. Vincent Wallace is in Newfoundland.

Frank H. Probert leaves for Oatman today.

W. R. Van Liew has returned to the Caucasus.

W. J. Lakeland is expected here from London.

E. C. Morse has returned to Portland, Ore., from Alaska.

E. C. Homersham has left England, proceeding to the Rand.

Joseph T. Terry, Jr., has been conducting flotation tests at the Magma mine, Arizona.

Walter H. Wiley is one of the expert witnesses in the Elm Orlu case at Butte.

Henry K. Klingender has gone to Oatman, Arizona, from Salt Lake City.

J. Parke Channing visited the Oatman district, Arizona, during the week.

Dorsey Hager has changed his address to 216 Lynch Bdg., Tulsa, Oklahoma.

Roscoe F. Allen is returning to Montana from the Rosario mine in Honduras.

Louis S. Cates is on a visit to the Nevada Consolidated mines at Ely, Nevada.

Charles MacC. Anderson, owner of the *Mexican Mining Journal*, is at Chicago.

R. M. Raymond has gone to London, expecting to return to New York in December.

W. H. Aldridge is at the Mason Valley mines, Nevada, but is expected here next week.

Ben. S. Revett was at Oatman, Arizona, last week, and has now returned to San Francisco.

Benj. F. Tibby has opened a petrological laboratory at 4 Caithness apartments, Salt Lake City.

William C. Russell has taken the management of the Carriman Mining Co. operating the old Caribou property in Boulder county, Colorado.

W. R. Thurston has been appointed manager for The Mine & Smelter Supply Co.'s Salt Lake City branch. F. E. Marcy, former manager, will still be associated with this company, devoting his efforts to the selling and developing of the Marcy ball-mill.

Schools and Societies

The number of students registered at the College of Engineering of the University of Illinois on November 1 is as follows: architecture, 166; architectural, 164; ceramic, 65; civil, 196; electrical, 257; mechanical, 242; mining, 30; municipal and sanitary, 28; and railway engineering, 44; a total of 1192. This does not include the number of engineering students registered in the Graduate school. The classes included 337 freshmen and 255 seniors.

The program (subject to revision) of the meeting of the Columbia section of the A. I. M. E. at Wallace, Idaho, on November 19-20, is as follows: technical session on first day: 'Progress in Ore Dressing,' by D. W. Buckby, and discussion; 'Mine Accounting,' by J. E. Chapman, and discussion; 'Zinc Smelting and Smelter Rates,' by W. E. Henry, and discussion. On the second day there will be a trip to the Interstate, Tamarack, and Success mines, a business session, an election, and banquet. A special invitation has been extended to the Montana section.

THE METAL MARKET

LOCAL PRICES

San Francisco, November 11.

Metal.	Cents per pound.
Antimony	37
Electrolytic copper	19
Pig lead	5.40— 6.60
Quicksilver (per flask)	$100
Spelter	17
Zinc-dust, 100-kg. zinc-lined cases	25

There is no spot market for zinc-dust, and delivery in May next is quoted as above.

ORE PRICES

Antimony: market irregular, 50 and 60% products, free from deleterious impurities, per unit.....$1.60 and $2
Magnesite: per ton $30
Manganese, 50% metal, 8% silica, per ton..... 12
Molybdenite: 90% MoS_2, per pound..... 1.50
Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....$35—40

New York quotes $41 per unit for 60% tungsten ore, prompt delivery.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 11.—There has been heavy buying of copper; lead is very strong and active; zinc is firm on recent buying; sheet zinc is up to 17 cents.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Nov. 4	50.00	Sept. 29	49.29
" 5	50.00	Oct. 6	49.64

Silver is higher, and apparently stronger than for some months. On November 6 the steamer to China took metal worth $587,700, say 1,175,000 oz., from San Francisco. The Nipissing company at Cobalt shipped 327,223 oz. to London last week. Stocks in London are 15,000,000 oz. India and China are small market factors at present. English and Continental coinage has steadied the market.

COPPER

Prices of electrolytic in New York, in cents per pound.

Date.		Average week ending	
Nov. 4	18.00	Sept. 29	17.87

May	13.97	18.71	Nov.	11.75	....
June	13.60	19.75	Dec.	12.75	....

Exports during the week ended October 23 totaled 15,229,219 lb., worth $2,832,827. France took 5,341,186; Italy, 4,356,061; England, 3,198,999; and Russia, 1,680,857 lb. Imports amounted to 2,414,325 lb., valued at $365,717. Brass exports for eight months total $26,602,575, compared with $4,559,204 in 1914.

Michigan mines produced 24,900,000 lb. in October, the same as the Anaconda company.

Kennecott produced 10,000,000 lb. in October, with $1,300,000 profit.

Cerro de Pasco is yielding at the rate of 60,000,000 lb. per year.

East Butte is making $2,000,000 per year, equal to $4.75 per share. The debt of $500,000 will be paid on December 1.

ANTIMONY

Quotations are unchanged at 35 to 36c., duty paid, and some fair-sized sales have been made at these high prices. Some of these have been on foreign account, especially to Canada, although domestic munitions makers have been buyers also. A good deal hinges on the opening of the Panama Canal as to when the market will become easier.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date.		Average week ending	
Nov. 4	15.25	Sept. 29	14.23

June	4.84	22.20	Dec.	5.40	....

Eight months' exports total 159,839,567 lb., worth $16,419,720, against 8,869,528 lb. and $596,225.

It is reported that the Anaconda company is to erect at Great Falls a zinc smelter of 40,000,000 monthly capacity.

Zinc-ore prices at Joplin were higher last week. The output of the region was 6322 tons blende, 263 tons calamine, and 832 tons lead, averaging $90.23, $61.38, and $56.09 per ton respectively. Total value, $633,555.

The American Spelter Corporation has entered the field of production and selling metal. It owns no mines, but buys ores for its smelter at Kusa, Oklahoma.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Nov. 4	5.00	Sept. 29	4.50
" 5	5.00	Oct. 6	4.50

The St. Joseph Lead Co. will pay a quarterly dividend of 15c. and an extra of 10c. per share on December 15.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Date.	Week ending		
Oct. 13	92.00	Oct. 27	93.00
" 20	92.00	Nov. 4	97.50
		" 11	100.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	95.00

June	30.72	40.26	Dec.	33.60	....

Tin is strong at 36.50 to 37.50 cents.

At the present income the American Zinc, Lead & Shelting Co. is earning $50 per share.

The Butte & Superior earned $11 per share in the third quarter, against $4.25 in the previous one.

Aluminum in New York is quoted at 54 to 57 cents.

Eastern Metal Market

New York, November 5.

The entire market has been good during the past week, both as regards activity and prices. All the metals are higher, and are showing considerable strength. Their course is more like that in iron and steel than has been the case in recent weeks. Copper was sold in large volume, especially Lake, the producers of which booked business heavily and did not scare consumers by advancing prices too rapidly. Later electrolytic became active. Zinc has advanced both at London and New York, and a large business has been done. The demand for galvanized sheets is brisk, prices have been advanced, and this will mean an outlet for prime Western spelter. Lead is holding firm at a new quotation of 5c., New York. Tin is moving well, and the New York quotation has touched 36c. Antimony is steady at the new high level. Aluminum continues scarce and strong at around 55 cents.

The boom in the steel trade is reaching gigantic proportions. In the production of pig-iron October broke all records, inasmuch as the daily output exceeded 100,000 tons. The production of coke iron in the 31 days of October was 3,125,491 tons, a monthly total never equalled before. The steel companies produced at the rate of 73,595 tons per day, their total for the month being twice that of January. Demand for foundry pig-iron, which has lagged behind that for steel, is now developing fast, and its prices are advancing. Bars, plates and shapes are technically quoted at 1.50c., Pittsburg, but in every district big premiums over this base are being obtained, and the consumer is lucky if he finds a mill that will accept this order at any figure. Added to the enormous business originating from war sources, from other foreign demand and industrial requirements, are the needs being made known by the railroads. They are fast placing orders for locomotives, cars, and rails. The Pennsylvania railroad has placed 175,000 tons of rails for 1916 delivery. Needless to say, prices of miscellaneous steel products such as pipe, nuts, bolts, rivets, etc., have advanced substantially.

COPPER

It is more than ever apparent that in the closing days of October a big business was done in Lake copper at about 17.87½c., cash, which was the price quoted for electrolytic, also. The Lake producers pursued what the trade considers a wise course, in that they did not immediately raise their prices when the buyers came in the market strong, but continued to book orders until commitments for several million pounds were on their books. It is conceded that there is good money in copper at 17.87½c. Early this week producers of both Lake and electrolytic were asking 18 to 18.12½c., cash, but it was pretty well understood that they would accept ¼c. lower. Now they are asking 18.12½c. full terms. A notable feature of the situation is that second-hands either have little copper to offer, or are holding tightly what they have. They evidently do not consider that the time for profit taking has arrived, and this is significant in view of the fact that it is as students of the market that they live. At the present time there is a good volume of inquiry, both domestic and foreign, before the trade, the bulk of it, of course, coming from the manufacturers of munitions. Electrolytic at London has gained £1 in the past few days, and now stands at £89. Discussing the London market at October 15 it is stated that the total supply of copper in Europe on October 16 (German supply estimated) amounted to 28,940 tons, against 34,106 tons on September 30, and 37,275 tons on September 15, indicating a gradual decrease in stocks. October exports showed a betterment, amounting to 23,657 tons. Total exports since January 1, 1915, (10 months) exclusive of Southern and Pacific ports, amounted to 210,320 tons, against 313,064 tons in the same period of 1914, a falling off of 102,744 tons.

Contracts involving upward of 50,000,000 lb. of copper were closed on November 5. It is understood that the metal will be used in the electrification of the Chicago, Milwaukee, & St. Paul Railroad system, and the deliveries will run well into next year. The British government purchased about 8,000,000 lb. for war purposes. In both purchases electrolytic predominated. The prices paid ranged from 18 to 18.12½c., 30 days, delivered. The heavy business caused quotations to advance to 18.25 to 18.37½c. full terms.

An important development in the copper field is the selling of the metal in Great Britain by the A. S. & R. Co., direct from stocks maintained in London, and through its own selling representatives. In New York the Baltimore Copper Smelting & Rolling Co. is selling sheet copper direct from its warehouse.

ZINC

This metal has advanced both at London and in New York. The London market advanced £2 October 28 to £70 10s.; on the 29th it rose another £1 to £71 10s.; November 1 to £73, while on the 3rd it went to £76, or over 15.50c. It is now £77. The New York market advanced with the higher prices abroad, and at all times there was a fair amount of business. The best trading always is done on a rising market, although it must be admitted that in this case there is a large amount of feeling over the prices of spelter. With spot metal about 15.12½c., November 3, prompt deliveries of prime Western were quoted at 14.75 to 15c.; December at 14 to 14.50c., and January 13 to 13.50c., and February and March at 12.50 to 13 cents.

It is likely that less will be said about over-production in the next few months. Winter weather, which is not far off, is not conducive to full operation at the mines or smelters, while it also is pointed out that many of the retorts have been overworked, and must shut down for repairs. Brass-mill special and the other high-priced grades are declining, but the brass special commands ½ to 1c. premium. One reason for the easier state of choice grades is that foreign specifications for cartridge metal are less strict. October exports totaled 6164 tons.

Sheet-zinc has risen to 17c. f.o.b. smelter, 8% discount for cash, carload lots.

LEAD

The action of the A. S. & R. Co. in advancing its quotation $3 per ton, or to 4.90c., occasioned genuine surprise in the trade, for, while the market bore a superficial appearance of strength, it was known that second-hands and the smaller producers were shading prices. The price went to 5c., New York on November 4. The independents followed the leading interest, and at present the market is firm. The advance stirred the interest of domestic consumers, and some of them began to sound the sellers, evidently in anticipation of another advance. Some large foreign sales have been made. London reports that large quantities will be shipped to Archangel before the close of navigation, while inquiries for shipment *via* Vladivostock are in the market. Exports from Atlantic ports in October totaled 4106 tons.

TIN

Deliveries into consumption in October were large, amounting to 4900 tons. Deliveries since January 1, 1915, aggregate 40,575 tons, against 37,200 tons in the same period of 1914, an increase of 3375 tons. In stocks and landing at the end of the month was 2144 tons, while the quantity afloat was 5543 tons. The arrivals at Pacific ports, destined for the East, amounted to 500 tons. In the last few days of October prices started on an upward trend, and 35c. was reached on October 29, while on November 1 and 2, the quotation was 36c. The market here and in London is sensitive and responds to the slightest fears.

MINING DECISIONS

Mining Contract—False Representations

Where a plaintiff sought to recover a payment made on a purchase of a mine, alleging as grounds for recovery a false representation made to induce his purchase, to the effect that a certain vein existed at a certain level, it is sufficient that he show that the vein did not as a matter of fact exist there, and testimony offered by the defendant as to the value of the mine was wholly irrelevant and properly excluded.

Cohen *v.* Stockton (California), 151 Pacific, 741. Aug. 27.

Oil Lease—Forfeiture Denied

An oil lease contained a provision that if oil were discovered, the lease should become effective for 25 years. The assignees of the lessee drilled a well and discovered oil, but afterward discontinued operations owing to the failure of the supply. In a suit by the lessor to cancel the lease it was held that the condition of the lease was satisfied when oil was discovered, and that a mere discontinuance of operations for a period of six months did not constitute an abandonment of the lease or warrant a forfeiture.

Fisher *v.* Crescent Oil Co. (Texas), 178 Southwestern, 905. June 26, 1915.

Coal Lease—Provisions Construed

Under a lease granting the right to mine and remove all coal and veins of coal upon certain property, requiring that pillars of coal should be left sufficient to support the roof so that at the expiration of the lease the mines and improvements would be in good condition for future mining, the lessee was held entitled to remove the coal in the pillars after he had mined all the other coal, as the only purpose of the restriction would then have been subserved, namely, to preserve the property as a workable mine so long as there was any coal to mine.

Miles *v.* N. Y. S. & W. Coal Co. (Pennsylvania), 93 Atlantic, 397. July 3, 1915.

Mineral Rights—Title by Prescription

Where an owner of the surface who was also one of the tenants in common of the mines and minerals therein, conveyed the whole of the property to one who recorded his deed, took possession of the entire property, and by himself and his successors continued in exclusive possession under such claim of title for more than 20 years prior to petitioner's acquisition of title thereto, and operated the only mine on the property, the petitioner as successor in interest had a perfect title to the whole of the premises by adverse possession, as title to mines and minerals may be acquired by adverse possession, not only by the surface owner, but by one having no interest in the surface.

Couch *v.* Armory Commission (New York), 154 New York Supplement, 945. August 25, 1915.

Mining Partnership—Dissolution

A grubstake agreement provided that the partner furnishing the capital should have an undivided quarter interest in mining claims in Alaska, and on the same day a deed was executed to that partner conveying an undivided one-fourth interest upon certain considerations. Thereafter the working partners assigned their interest to others, who upon a suit for dissolution and accounting, brought later by the grubstake partner, sought to exempt their interests from levy for indebtedness. Held, that all indebtedness should be paid from partnership assets and the several interests charged on the basis of their proportionate indebtedness at the date of the levy. Upon distribution the partners were to share equally.

Lesamis *v.* Greenberg (Alaska), 225 Federal, 449. Aug. 9.

BOOK REVIEWS

Field Analysis of Minerals By G. D. McGrigor. P. 86. *The Mining Magazine*, London, 1915. For sale by the Mining and Scientific Press. Price, $1.

Quick and reliable methods of field analyses are often required, and in this book of pocket size, intended for the prospector, mining engineer, traveler, and student, should be found many useful tests. The author thinks that some of the methods might shock those who work in proper laboratories, but as they served him well, they will be found of practical use in the field. Apparatus necessary for the work is detailed; so is the appearance and physical properties of minerals. The use of the blow-pipe, which is one of the author's principal methods of determination is given considerable space, including the reactions. Simple wet analyses are described, and a summary of reactions with hydrochloric acid. Generally a handy little reference book.

Mechanical Drawing. By James D. Phillips and Herbert D. Orth. P. 278. Ill., index. Scott, Foresman & Co., Chicago and New York. For sale by the Mining and Scientific Press. Price, $1.75.

This work is primarily a class-room textbook. Directions for the drawing of 'plates' are given with the text and an outline for a course in mechanical drawing is given at the end of the book. The first chapter is devoted to a brief treatment of 45-degree perspective drawing, so brief that the average student would have great difficulty in comprehending the subject without the guidance of a skilful instructor. The general principles of orthographic sketching are then discussed. The mechanical details of drafting are then considered, beginning with pencil-work, and then tracing and blueprinting. Instruments and materials of drawing are then discussed, and then the various signs and other conventions in common use. A chapter is devoted to lettering and one to 'Advanced Drawing,' the latter dealing with the preparation of complete working drawings of several rather complicated machine parts. Some space is also devoted to isometric drawing, and the last chapter gives some suggestions to instructors using the volume as a text book.

Dana's System of Mineralogy. Third appendix to sixth edition. By William E. Ford. P. 87. Illustrated. John Wiley & Sons, Inc., New York, 1915. For sale by the Mining and Scientific Press. Price, $1.50.

This volume completes the well-known work to 1915. The sixth edition was published in 1892, with the first and second appendices in 1899 and 1909 respectively; the third covers a period of six years. Generally, the new work is similar to the previous ones. That investigators in mineralogy have been active during the last six years is evidenced by the size of this appendix, as well as by the fact that about 180 new mineral names have been proposed. Of these minerals which have received new names about one-third are apparently well established species. The others are clearly to be considered as varieties of already well-known species or, because of their incomplete investigation, must for the present be considered of somewhat doubtful authenticity. The division of the new names into the three classes: (1) of varieties, (2) of doubtful species, (3) of established species, is indicated by the three kinds of type used in the classified list to be found in the book. A bibliography of important volumes published during the period is given. In this term the most important new development in mineralogical investigation is the use of X-rays in studying molecular structure of crystals.

NEW MACHINES AND DEVICES

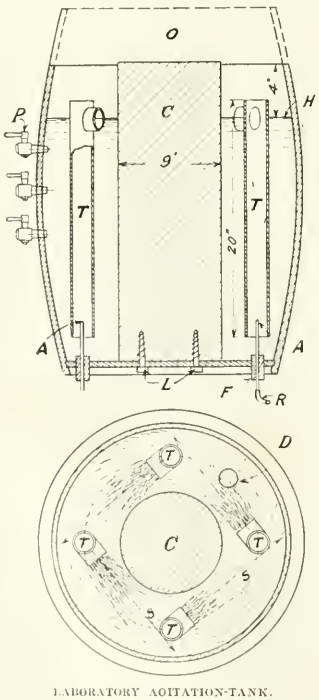
Information based on letters and catalogues from manufacturers.

Laboratory Agitation-Tank

A tank equipped to use the Parral system of agitation, and of a size suitable for laboratories or small test-plants, may be cheaply made from an ordinary wooden barrel, as shown in the accompanying illustration, which is an acid-proof tank for experiments in leaching of copper ores:

O. Is the top portion of the barrel, about 5 or 6 in. to be cut off.

C. Is a central filler made round from a solid piece of 10 by 10 in. timber. The object of this is to take up space in the



LABORATORY AGITATION-TANK.

tank so as to reduce its holding capacity, and therefore the necessity of pulverizing so much pulp for a test. A barrel equipped as shown has a holding capacity of 60 lb. of pulp, with 120 lb. of solution.

T. Is the transfer-pipes, which in acid-proof tanks are of 2-in. lead pipe.

A. Is the lead pipe air-nozzle. This is inserted through a wooden plug F, which drives snugly into holes bored in the bottom of the tank, the lead nozzle extending up about 2½ in. into the transfer-pipes.

R. Is a rubber connection wired on to the air-nozzle. This connection extends upwards to the iron air-pipe placed above the pulp-level H.

P. Is the wooden plug-cocks which are fitted staggered into the side of the tank at various heights for drawing off the clear pregnant solution, when the solids are settled on the bottom of the tank.

D. Is a plugged hole in the bottom of the tank, through which the treated charge may be drawn off.

The tank is set on a rock about 18 in. above the floor for convenience in making the bottom connections, and drawing off the charge. Similar tanks with slightly different equipment suitable for making cyanide and oil-flotation tests may be made. Detail plans for the construction of experimental tanks of any size suitable for testing ores by either acid leaching, cyanidation, or oil flotation will be furnished gratis by the Parral Tank System of Agitation, I. W. Hellman building, Los Angeles, California.

Commercial Paragraphs

CHARLES HARDY has established a business at 50 Church street, New York, as a broker in antimony and antimony ore, tungsten metal and tungsten ore, copper ore, and other minerals. Mr. Hardy was engaged in this line in London for 12 years. In the course of his business career he has visited 40 countries.

The SULLIVAN MACHINERY Co. announces the removal of its St. Louis branch sales office from 705 Olive street to suite No. 2006 Railway Exchange building, where larger and more desirable quarters have been prepared. This change will enable the company to give still better attention to the requirements of its customers in the territory served by the St. Louis office.

During the week of November 1 to 6, the OLIVER CONTINUOUS FILTER Co., of San Francisco, has received orders for filters from the following mills: Chichagoff Mining Co., Alaska; Teck-Hughes Gold Mines Co., Swastika, Ontario, Canada; Duquesne Mining & Reduction Co., Duquesne, Arizona; Walker Mining Co., Portola, California; Calaveras Copper Co., Copperopolis, California; and the Federal Mining & Smelting Co., Wallace, Idaho.

In Bulletins L-530, L-531, and L-532, the LAIDLAW-DUNN-GORDON Co., Cincinnati, Ohio, a subsidiary of the International Steam Pump Co., of 115 Broadway, New York, describes its duplex power-driven Laidlaw feather-valve air-compressors (class PF and PF2), single power-driven Laidlaw feather-valve air-compressors (class RF), and gas compressors, gas expanders, and vacuum pumps for the recovery of gasoline from casing-head gas respectively. The compressors are belt driven from electric motors, the drive being short. Details are given of the construction of parts of the compressors. Those engaged in making gasoline from casing-head gas in California and other states will find the third publication of interest.

On October 25, the U. S. Bureau of Mines placed 'duPont Permissible No.1' on its list of explosives permissible for use in coal mines. It belongs to Class 1a, ammonium nitrate, and is permissible only when used with detonators, preferably electric detonators, of not less efficiency than the No. 6. It is manufactured by the E. I. DU PONT DE NEMOURS POWDER Co., Wilmington, Delaware. On November 4, the U. S. Bureau of Mines placed 'Red H No. 8' on the list of explosives permissible for use in coal mines. It belongs to Class 1a, ammonium nitrate, and is permissible only when used with detonators, preferably electric detonators, of not less efficiency than the No. 6. It is manufactured by the HERCULES POWDER Co., Wilmington, Delaware.

EDITORIAL

T. A. RICKARD, Editor

IT'S an ill wind that blows nobody good. The closing of the Panama Canal, by the slide in the Gaillard cut, has caused a congestion of traffic on the coastwise railroads. We have already learned to appreciate the usefulness of the Canal.

BOLIVIA and Peru are both considering the imposition of heavy taxes on mineral and metal exports. A struggle is in progress between the Governments and the mining interests, which are in danger of being crippled by undue exactions.

TALK of "investing" money "on conservative lines" in mining is usually the preface to a wild-cat scheme. The people who know most about mining are aware that it involves risk, but that the risk can be compensated, and sometimes more than compensated, by the gain.

FLOTATION at the Broken Hill Proprietary mine, New South Wales, treated 2,847,815 tons of tailing from November 1903 to May 1915. This yielded 708,149 tons of concentrate containing about 47% zinc. Now, however, that the process is being applied in this country on a growing scale, it is destined to eclipse anything heretofore done in Australia.

J. C. ROBERTS has been appointed to the new chair of Safety and Efficiency Engineering recently established at the Colorado School of Mines in memory of Joseph A. Holmes. The choice is a happy one; it is one of which Holmes himself would have approved strongly. The new professor at Golden has a host of friends in the mining profession, all of whom are glad to note the honor conferred upon him, in fitting recognition of his faithful work in behalf of the safety propaganda.

ASBESTOS is a beautiful mineral, valuable as a non-conductor of heat. The American source of supply is the eastern part of the Canadian province of Quebec. In this issue we give our readers two allied articles on the subject, one by Mr. F. H. Mason, on the technology of the industry, and another by Mr. P. B. McDonald on the mining of the mineral. We may note that promising discoveries of asbestos have been made recently in Trinity county, California.

SPECIAL arrangements for overcoming a large inflow of water in the Commonwealth mine, in Arizona, are described by Mr. Edgar A. Collins on another page of this issue. The article, as is usual with anything Mr. Collins sends us for publication, is eminently practical and useful. The two main points to be noted are that (1) instead of sinking a main hoisting-shaft in the broken wet ground within the vein, an incline was sunk in the closer-grained rock of the foot-wall; (2) a steel-hinged door of special design was placed in the cross-cut, between concrete pillars, to hold back and regulate any extraordinary flow of water, so that the pump might not be flooded. Details of the various pumps, their cost, and their advantages are given. We commend the article to other mine managers.

AMONG the inventors of flotation processes the following describe themselves as American: Hezekiah Bradford, John Tunbridge, Carrie J. Everson, E. B. Kirby, H. E. Wood, D. H. Norris, J. D. Wolf, T. J. Hoover, and E. H. Nutter; on the other hand, the Elmore brothers, H. L. Sulman, H. F. K. Picard, A. H. Higgins, and A. E. Cattermole, are English. C. V. Potter, A. J. F. De Bavay, and E. J. Horwood are Australians. A. P. S. Macquisten is Scottish. John Ballot is an Afrikander, Alcide Froment is Italian, and G. D. Delprat a Hollander.

CARRIE J. EVERSON, one of the pioneers of the flotation process, died at San Anselmo, California, on November 15 last year. We understand that this fact was ascertained recently in consequence of inquiry following the subscription of a fund in Colorado. It was intended to make a presentation to her, in appreciation of her service to the mining industry. Her own patents expired before the flotation process came into vogue in the United States, so that she derived no financial gain from them, although undoubtedly they served indirectly to stimulate the research and invention of others, now collecting royalties or trying to do so. At the time of her discovery, in 1885, at Denver, she was a school-teacher. Her brother was an assayer and it was in his office that she made the observation concerning the flotative action of oil on a pyritic concentrate.

REVISION of the Federal Land Laws as they apply to mineral locations is to be the subject of a meeting of mining men called for December 16 at Washington. This meeting is to be held under the auspices of the Mining and Metallurgical Society of America, with the cordial co-operation of the various mining associations throughout the West. The purpose is to demonstrate to Congress that those engaged in the mining industry earnestly desire a radical alteration of our archaic and discordant mining laws. However, it is not the intention to advocate specific reforms, or to draft any new laws, but to impress upon Congress the feeling of the industry

that something be done, for instance, by the appointment of a commission with power to study conditions in the mining regions and thus obtain the information required for intelligent legislation.

WE take particular pleasure in publishing a detailed and careful article on the cyanide treatment of flotation concentrate, by Messrs. Charles Butters and J. E. Clennell, both of whom are known wherever cyanidation is used for the winning of the precious metals. The results they give represent the outcome of an elaborate series of experiments on ore from the San Sebastian mine, in Salvador. This mine affords an example of operations in a locality far from any smelter to which the concentrate made by the flotation process might otherwise be consigned. As yet the important applications of flotation have embraced base-metal ores in mining districts linked to smelting centres, so that the local treatment of the concentrate has been a problem postponed. It is obvious, however, that in the case of gold and silver mines situated in localities distant from reduction works or relatively inaccessible to railway transport, it will be necessary to devise some method of converting the precious-metal contents of the flotation product into bullion. Therefore such investigations as these made by Messrs. Butters and Clennell are of wide and timely value. We hope that others will follow their example and be equally generous in giving information so useful to the profession.

Alaska Gold Mines

Mr. D. C. Jackling, as general manager of the Alaska Gold Mines, has reported to the shareholders, by means of an interview in the *Boston News Bureau*, that this great enterprise has encountered an obstacle, sufficiently unexpected to cause perturbation in the stock-market. He explains that some delay in the complete fulfilment of estimates has arisen from "an unlooked-for intrusion of low-grade schist on the 5th level." This was a part of the Gastineau-Perseverance mine from which the management "had expected to draw high-grade material with which to sweeten the known lower-grade ores to be mined near the surface." This 'horse' of schist is all the more disconcerting because numerous drill-holes had been driven all around it without detecting the fact that it was there, like a sunken reef in a tropic sea. Well, it does not mean shipwreck or anything like that; it means the vessel will lose a tide in entering port, that is all, but it is a warning to those who navigate the shallow waters of low-grade mining. Up to the end of October the company had treated 900,000 tons averaging $1.25, or 50 cents less per ton than the original estimate. The cost has been 60 cents, or 15 better than the estimate; while the loss in tailing has been 20 cents, against an expected 25 cents. The net result is a profit of 45 cents, in comparison with the 75 cents anticipated. The discrepancy is serious. Just now 5000 tons of ore is being treated daily, sometime next year it is expected to increase the production to 8000 tons per day, equivalent to, say, 2,800,000 tons per annum. This, on a profit of, say, 60 cents per ton, represents $1,680,000 per annum. The stock has sold at $40 during the current year; as the shares number 750,000, this represents a capitalization of $30,000,000, without including the bond issue of $1,500,000, which is convertible into still more stock. To those experienced in gold mining it is not necessary to say that a return of 5½% per annum is quite disproportionate to the risk inherent in this kind of speculation. A mine, even the biggest, is a wasting asset; to win $30,000,000 from the gold-bearing slate at Juneau it will be necessary, at a profit of 60 cents per ton, to mine and mill 50,000,000 tons of ore; at the rate of 2,800,000 tons per annum it will require 18 years to achieve such a result. And then we have not begun to estimate the further time and tonnage required to pay interest on the money involved. That is hopeless on such a basis. To pay 5½% and redeem the capital involved it will be necessary to double the estimated huge production of 8000 tons daily. In other words, a yield of 11% per annum, 5½% as interest and 5½% to apply on the redemption of the principal, on a valuation of only $20 per share—half the recent high price—will require 18 years of production at the present estimated tonnage and profit. And 5½%, of course, is no sort of a yield for a gold mine; all experience shows that 10% net is barely enough. Therefore we conclude that the original capitalization at $10 per share, for 750,000 shares, net was quite reasonable, but that the recent quotation of $40 was ludicrous. This is an example of a common happening, namely, the over-valuation of a splendid mine. More money has been lost in a few good mines than in a multitude of worthless ones, for the sums thrown away on the latter are small as compared with the inflation that befalls mines of extraordinary size or richness. This is due to forgetfulness of the fact that ore does not grow as fast as it is exhausted. Moreover, even when the managers or engineers of a mine take pains not to exaggerate, it appears to be considered proper for brokers and outside promoters to make what statements they please, the result being to transfer the money of the many to the pockets of the few. That is not the object of legitimate mining. We regret that a magnificent mining enterprise, the product of splendid engineering initiative, should have become the usual counter for a reckless share-dealing campaign. For that we blame the brokers in Boston, not the engineers at Juneau. We also blame the public for its gullibility, in face of the known facts of experience and the absence of technical information warranting the kiting of the stock. As Mr. Jackling says, the milling plant is the most efficient of its kind in existence, it represents a concentration of 800: 1 and the application of the special experience obtained by him and his coadjutors in the exploitation of the low-grade deposits of disseminated copper. The technical achievement is splendid, but it did not need another example to prove that over-valuation easily kills the fruitfulness of a low-grade gold mine. That was proved by the big deep-level schemes of the Rand,

where even a profit of $1 per ton afforded a precarious margin for a return on the big sums of money involved. Besides 'horses' of barren rock, there are caves, fires, and strikes to be faced in the course of a long-lived mine. Renewals of equipment and plant cut into nominal profits. Mining is a business subject to the laws of economics, and it prospers best when the engineer is deaf to the share-broker.

Concerning Talk

In a recent issue an observant correspondent undertook to prove that engineers do not talk enough. He argued that most of them were unable to do themselves justice in so far as they lacked the faculty to use words freely for the purpose of arousing the interest of others, particularly possible clients, in their affairs or the affairs they purposed to make their own. Apparently our correspondent considered that engineers fail to make themselves interesting to the non-technical, but highly financial, persons that supply the sinews of war in that industrial arena where the business of mining is promoted. "Talking will enhance the engineer," he says.

This is a new doctrine. Like many exaggerations, it contains a modicum of truth. Let us disregard the irrelevancies and dwell upon the suggestion that engineers should learn to express themselves in a clear and interesting manner to non-technical persons, and that the possession of any ability is enhanced in its practical value when other people are made pleasantly aware of it. Undoubtedly the ability of an engineer to explain a mining or a metallurgical operation to a client is apt to impress the latter with the engineer's powers. And the client won't be far wrong. Clear expression is preceded by clear thinking. Moreover the understanding of any operation or of any problem is furthered by the effort to state it in explicit terms and in logical sentences. An intelligible and pictorial presentment of an engineering operation is an excellent step in the thorough understanding of it, first by the engineer himself, and then by his client. One of the best ways of clarifying one's ideas on any subject is to try and explain it to another person.

Another phase of the question of talkativeness is the intensely human characteristic that in order to interest others one must be interested in them. No man is likely to speak convincingly unless he is keenly aware of his auditor. That means sympathy. The man who talks and gives information is likely to elicit information in return. One of the best ways of gaining knowledge is to give away the little that one has. That is where the talkative man scores, always supposing that he talks intelligently and to some purpose. Secretiveness meets with secretiveness. Moreover, talk gives form to thought as the surf shapes the pebble on the beach. Frank speaking about things in one's mind may lead to the formulation of good ideas and prevent the making of bad blunders. The ventilation of an idea often leads to fresh thought being brought to bear upon it. Two heads are better than one, even if one be a numskull, for the latter may serve as a strop on which to sharpen the edge of wit. When a wise man meets a blockhead, it is the part of wisdom to use the latter as a dull audience and think aloud in the effort to shape an idea or to arrive at a conclusion. The thought when spoken presents itself differently from the form it has while lying half-dormant in the brain. The presence of the blockhead, like the impurity in a chemical solution, may suffice to precipitate the thought into crystalline form.

Owing to diffidence or laziness some engineers talk but little and condemn those that talk freely. They may be reminded that it is speech, and not anatomical modification, that most separates man from the lower animals. It is man's supreme distinction that he can convey thought by words and perpetuate that thought by writing. Some of us fail to know or to be known for lack of this means of intercommunication. Like two castaways at the opposite ends of a desert island we gaze upon the sullen sea of life without cultivating the sympathy and understanding that can only come from a friendly interchange of experiences. Ah, there we have it: exchange of experience! The failure to make that exchange is the greatest engineering waste and the most obvious cause of inefficiency. To prevent that squandering of priceless knowledge, of men, things, and events, it is well worth while to encourage talk, more particularly among engineers, as a brother to a brother; a senior to a junior, to give advice; or a junior to a senior, to give enthusiasm.

The Withdrawn Oil-Lands

The recent organization, in San Francisco, of the Oil Industry Association, which is composed of the Californian oil operators affected by the decision of the United States Supreme Court affirming the Taft Oil-Lands Withdrawal Act of 1909, directs public attention to a crisis in Western mining affairs. This branch of the industry occupies a position of tremendous importance, not only in the commercial life of the Pacific Coast, where crude oil is burned instead of coal as a fuel for generating steam-power, and as a factor in the use of the automobile, whether for work or pleasure, but in the economics of the metal-mining industry, more particularly in the smelting of lead and copper ores. Indeed, nearly all mining operations near any railway benefit from the use of fuel-oil. It is evident that if the production of oil from unpatented lands is to cease, the burden of supplying established markets cannot be sustained by the yield obtainable from the patented lands alone, which, unfortunately, are not of extensive area. The lands affected by the decision are in the San Joaquin valley, which yields 80% of the 100,000,000 barrels of oil produced annually in California.

Crude petroleum is interwoven in a fundamental way with the social and business fabric of the Nation itself, for there has been created in the great Midway oilfield a Naval Petroleum Reserve, embracing 100 square miles and destined as a source of supply for our battleships of

the future. The Navy seems definitely committed to the use of oil-fuel: the results of a single battle in the North Sea last year has left no other choice. Thus the position is already complicated beyond all hope of a simple solution. Therefore the question has arisen, and will probably be projected into Congress during the coming winter, how far should the obligation of the State to the Nation prevail against the commercial interests of a particular State and its related territory? California, out of her abundance, can guarantee an oil-supply that will maintain a naval policy, at least to the extent of the useful life of the ships now built or in process of building, but will not the requirements for national defense formulated by those residing east of the Rocky Mountains prove too much for public acceptance here? This matter of oil reservation is but one phase of the broader question of conservation, embracing all the unappropriated or unexploited natural resources of the Great West; it is the grim spectre that stalks into the deliberations of every public organization west of the Missouri river, whether it be a Governor's conference, a Mining Congress, or the after-dinner talk of an engineers' club.

The immediate cause of this burden of perplexity is the now famous oil-land withdrawal of ex-President Taft on September 27, 1909. It appears that influence had, without avail, been brought to bear upon Congress during the sessions of both 1906 and 1907 to remedy conditions existing in certain oilfields where title was being acquired by agricultural and other forms of scrip entry, in place of the more expensive method of proving the land by drilling and obtaining a mineral patent outright; in other words, to the subversion of the mining law. The continuance and spread of this practice caused the United States Geological Survey to recommend the withdrawal of large tracts in the favored oil-regions pending this further classification, and the passage of additional laws that would protect the petroleum interests adequately. The acquisition, too, by the Pacific railroads, through their land-grant titles, of vast tracts of mineral land contrary to both the letter and the spirit of the granting acts, as well as the patents flowing therefrom, contributed its quota of resentment against the manner in which oil-lands had been lost. Unfortunately the executive act of 1909 came at a time when the consumption of oil had about passed production, following years of depression due to over-production, and when ascending prices had caused a decided expansion in the search for new pools of oil to satisfy the expanding markets. On that day, the now fateful September 27, 1909, the President, with the authority implied, but not specifically given, by Congress, withdrew from all forms of settlement and entry approximately 3,000,000 acres of presumed oil-lands in California and Wyoming, and possibly some other States. The apparent and implied purpose of the Act was in aid of further classification of, and proposed legislation for, these lands. This legislation thus far, in six years, aside from the Pickett Act in 1910, has failed to materialize; the chief result ensuing therefrom being the suspension of the placer-mining law (except where claims were already 'valid' on September 27, 1909) as applied to the acquisition of petroleum lands, a provision that had been specifically enacted some years previously. In February 1915 the United States Supreme Court affirmed the legality of the Taft withdrawal, and thereby confirmed the virtual suspension of the laws governing prospecting for petroleum on the public lands believed to be most favorable to development, though they might still apply to such lands as the Geological Survey had not yet provisionally classified as valuable for oil. To give meaning, however, to the Supreme Court's decision, an Act was passed by Congress ten days later, appropriating $50,000 wherewith to follow up the Government's now legalized oil-interest in California and Wyoming. The suits under way in these two States follow from this last enactment. Thus it would seem that it behooves Congress to give its immediate attention to rectifying an acute anomaly, acute not so much because many oil operators (and indirectly the consuming public) are victimized by the legalizing of the first order of withdrawal, but because of the practical suspension of the laws governing the entry upon, and acquisition of, oil-land.

Some additional lands have been withdrawn by the President since 1909, with the direct authority given by Congressional act (the Pickett Bill of June 25, 1910), and much that was originally withdrawn has been restored to entry—all upon the recommendations of the Geological Survey. At present there are withdrawn in California approximately 1,500,000 acres, and in Wyoming 500,000 acres. Of the area withdrawn in California over two-thirds is patented land and is not affected, and of the remaining third, or the unpatented acreage, only 10%, situated in and contiguous to known oil-fields of commercial importance, is thought to be claimed by oil-operators at this time. So far as the public is immediately concerned, therefore, and so far as the industry is directly involved, the contest is being waged over some 50,000 acres only of real and prospective oil-land (while prospecting over 450,000 acres has been shut off), having a possible value of $50,000,000, instead of the 3,000,000 acres alleged to be at stake. The present production from the lands affected is said to be 1,000,000 barrels per month. A situation, grave in itself has been made more serious by the entrance of the United States Navy with its demands and requirements for oil-fuel. Of the $100,000,000 annual value of California's mineral products, $50,000,000 is credited to crude petroleum alone. It would seem that any difficulty thus threatening to cripple an industry of such magnitude, particularly if that industry be a basic one affecting the free flow of commerce, should and must have the immediate and serious consideration of Congress. The cause of the oil-men who persisted in the pursuit of their assumed rights and are now in an awkward position may have emphasized this crisis, but their cause, a personal one, is of secondary importance to the bigger issue: the need for an adequate, just, and equitable law governing the acquisition of all the unappropriated and unexploited resources of the Great West, the remaining untapped reserves of mineral wealth in the United States.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Strike in Arizona

The Editor:

Sir—I have just received your issue of November 6, and the editorial headed 'The Strike in Arizona' has been brought to my attention.

In the volumes emanating from the editorial room of a scientific publication of authority it is fair to expect that, whatever may be the individual opinion expressed, the facts on which it is based shall be unassailable. It is regrettable that through lack of knowledge of actual conditions existing in the Clifton-Morenci district prior to the strike, the assumptions and inferences in the article above referred to are alike misleading.

You state that underground labor is paid as low as $1.75 per day on 13-cent copper. During the depression of 1914, when copper sold for less than 13 cents per pound, it became necessary for the Detroit Copper Mining Co. to reduce its output and economize in every possible manner. In order to maintain its organization and avoid the necessity of throwing a large part of its employees out of work, it was arranged that a reduction of wages below the normal should be made, and all employees were given work four shifts per week instead of six. Under these conditions the wages paid for a 7-hour shift for Mexican miners was $2.36 per day, and for Mexican 'muckers' $1.87, American miners and 'muckers' receiving 50 cents higher pay.

When in February last the market price for copper reached 14 cents a sliding wage-scale was put into effect which increased wages for every one cent rise in the price of the metal. Therefore, when the strike was declared on September 11 Mexican miners in the district were receiving $2.73 and 'muckers' $2.13 per day of 7-hours shift. This scale of wages is higher than that paid in any other purely Mexican camp in the United States.

You state that "the rate of wages might not have precipitated a strike if the cost of living had not been increased to the Mexicans by the fees exacted for hospital and water service, and by compulsion to buy their food and clothes at the company store." Analyzing this statement in accordance with the facts; there was no increase in the hospital fees, the employee paying exactly the same amount to the Hospital Department, namely, $1 per month for a single man and $1.50 for a married man, as has been in force for years. The charge for water service, which is incorrectly assumed to have been paid to the mining companies, remained at $1 per house per month as formerly.

The employees of the large operating companies of the district are not compelled to deal at the company stores, but have the option of purchasing their food and clothing from merchants throughout the district, who are conducting their business independently of any company control. While it is an admitted fact that the store business of mining companies has been a cause of irritation with some employees, due to a lack of appreciation of what the company store means as a factor in maintaining low prices and decent living conditions in mining communities, where there is competition by outside merchants the company store cannot but be beneficial to the wage earner. It has been fully substantiated that in mining camps in the southwest where no company stores exist the prices of the necessities of life are higher than where a large and efficiently managed mercantile branch of the mining company is operated on a reasonable basis of profits. In the case of Morenci the mercantile business is conducted by the Phelps Dodge Mercantile Co., whose financial report of operations is published in detail in the annual statement of Phelps, Dodge & Co., it shows that the net profit to the Company for the year 1914 was 8.38% on the gross sales and transfers.

You make the statement that the Mexicans complain that the wages paid previous to the strike varied under different foremen. This complaint, if made, has not reached headquarters. It is so obviously absurd as to merit but little consideration. In large mining companies such as those involved in the labor disturbance referred to, the foremen do not set the men's rates of wages nor do they have anything to do with the payment thereof.

As regards the ability of the mining companies to pay higher rates of wages, you state "regarding the Detroit Mining Co. not much is known, it being a subsidiary of a much larger corporation, Phelps, Dodge & Co." It is surprising that you should have expressed ignorance regarding this subject, as the annual statements of Phelps, Dodge & Co. are readily available, and the operations of each of its subsidiaries are separately reported. In fact, on reference to your files you will find that you analyzed these operations last spring. The figures shown as net profits from the Detroit Copper Mining Co. for the year 1914 is $602,318. It might be interesting to state that the demands of the Western Federation leaders were for a wage which would have increased the cost of producing copper for that year by $608,000.

Admitting that as always the employees of a large

operating company have grievances, minor or otherwise, which it is proper and just should be given hearing and consideration, it is a fact that in the present case the employees in the Clifton-Morenci district were receiving in August last higher wages than had ever before prevailed in the district, and prior to the organizers of the Federation shutting down the operations of the companies, had made no requests for a meeting with the managers, nor had they presented any grievances whatever.

The controversy between the companies and their employees has been from the inception, and is today, simply whether the district shall be dominated by the influence of the Western Federation of Miners or shall continue as in the past to operate as an open camp. The questions of the wage scale and other minor grievances have been interjected simply for popular effect and to obscure the issue, and do not alter the cardinal principle of union recognition.

I presume the conditions which initiated and the subsequent progress of this strike are absolutely unique in industrial disputes between labor and capital. The mining companies were forced to suspend operations by an active and aggressive minority who terrorized their peaceable employees, and that without having been given an opportunity to even hear, far less discuss, any question of grievance. The mines and reduction plants were picketted and all representatives of the owners were and have been since September 11 refused admission even for inspection. Only by the departure of the managers from the State, through advice of their legal counsel, has violence and outrage been minimized, and the district now remains almost depopulated through the exodus, voluntarily or otherwise, of the law-abiding element of the people.

Any commentary on a political condition which denies the protection of the law to the industry which has so actively developed the resources of the State would be superfluous.

WALTER DOUGLAS.

New York, November 11.

[Of course, we are glad to give space to Mr. Douglas's rebuttal. He makes our statements apply directly to the Detroit company, while, as a matter of fact, we referred to minimum wages paid in another of the group of three mines affected by the strike. Our information came to us at first-hand from a responsible member of the profession recently at work in the district. As to the fees for hospital and water service, Mr. Douglas has mis-read our remark, which was not that these fees had been increased lately, but that "the cost of living had been increased to the Mexicans by the fees" thus levied. The charge for water-service, like other charges, may be small, and it may not be paid to the mining companies, yet it is a source of irritation to ignorant laborers, such as the Mexicans. We believe the statement as to a variation in the wages paid under different foremen is true, although it may not apply to the Detroit mine, as Mr. Douglas states. We hope that the mining companies will succeed in their refusal to recognize the Western Federation of Miners, but we doubt whether the principle of collective bargaining, as regards their own employees, can be ignored successfully.—EDITOR.]

Flotation on Gold Ores

The Editor:

Sir—I was very much interested in the interview with Mr. Butters appearing in your issue of August 21, 1915.

Flotation promises in the future to take a very important part in the treatment of sulphide gold ores. It is going to be a serious competitor to the cyanide process, especially where the precious metals are locked up within the sulphides. At the present time there are many mills treating low-grade gold ores in California, Alaska, and Korea that employ only amalgamation and water-concentration (tables and vanners), the tailing being too low for a further profitable treatment by cyanidation.

Concentration results will no doubt in the future be improved by the application of flotation to the treatment of the slime. The extraction of sulphides from the sand can be done cheaply and efficiently on Wilfley or Card tables. The weakness of water-concentration methods during the past has been with the treatment of that product passing a 200-mesh screen commonly called 'slime.' The best concentrators on the market today make only an incomplete saving of the fine float sulphide mineral which in many cases accounts for a good part of the gold escaping in the final tailing. Flotation is the remedy. The Suan gold mine in Korea is an example.

There are a number of low-grade sulphide ores (Oriental Consolidated in Korea and the Alaska Treadwell) that do not require to be crushed finer than 25-mesh in order to free the sulphides from the gangue. Would such a coarse product, where a considerable portion of the sulphide remains on a 40 or 50-mesh screen, be suitable for an all-flotation process? I am inclined to favor in such cases a combination process consisting of tables for sand and flotation for slime.

Where the sulphide minerals are finely disseminated throughout an ore and comparatively fine grinding is necessary, I should think an all-flotation process would then be in order. However, those of us who have to do with the design of plants would insist upon large-scale tests before deciding on a flow-sheet. It is money wisely spent where big sums of money are involved in the final plant.

A. E. DRUCKER.

La Salada, Colombia, October 9.

ANTIMONY is being mined in Bolivia, stimulated by high prices, to the amount of several hundred tons monthly of 60% ore. The deposits are irregular veins in slate, and the mining methods are crude, consisting in extracting what can be seen, regardless of the future. Practically no capital has been invested in operating the mines, native methods being employed.

Handling Drill-Steel

By P. B. McDONALD

The old method of handling drill-steel at a mine, namely, getting the dull steel to the sharpening-shop on surface and the sharp steel to the miners underground, was careless. As little attention as possible was spared for this purpose. In some cases, each miner carried his dull steel to the shaft when he went up at half-shift, took the bundle up on the cage, and carried it to the blacksmith-shop; the sharpened steel he carried back in the same manner.

There are many objections to this primitive method:

1. A miner should have as many miscellaneous worries removed from his shoulders as possible; his job is to mine, and he has enough to do if he does that well.

2. It is dangerous for men to crowd into a cage when each has an armful of drills to carry; a stray drill sticking into the shaft may wreck the cage.

3. If the shop is quite a distance from the shaft, as it frequently is, the task of carrying a dozen lengths of drill-steel there, perhaps through snow or rain, is exhausting to a man in wet or thin underground clothes.

4. When a miner has to carry his own steel, he will continue to use dull drills as long as possible rather than change, thus working with poor tools.

Another method of collecting and distributing steel is to have one or more 'drill-boys' make the rounds of the mine, hoisting and lowering the steel without danger of accidents, in much the same manner as 'powder-mongers' distribute explosives underground. There is not so much objection, however, to the miners carrying dull steel to the shaft underground and sharp steel from the shaft to their places of working, so long as that is the limit, because they have to walk in and out to these places anyway. Where the mine has but a one-compartment shaft, it is a good plan to utilize the lunch-hour or any periods of time between shifts to have the drill-steel raised and lowered.

Among the aids to the handling of drill-steel in use at large mines are the following. Wooden racks, either horizontal or vertical, are built on each level near the shaft, where sharp steel is kept always on hand arranged in the different racks according to lengths; then, whenever any miner wants sharp steel he merely carries out his dull drills to the shaft-station and takes back sharp sets; the racks are kept full and the dull steel is taken to surface by a special man or two. To convey the steel between the shaft and the sharpening-shop, horses and wagons can be employed advantageously; one mine has a special wagon-box which is removed at the shop by a traveling-crane and lifted handily to the drill-sharpeners. Another aid to good work by the miners is to keep each contract's or gang's steel separate. Numbers corresponding with the contract are stamped on the shank of each drill, and when sharpened each contract's drills are packed neatly in a 5-inch iron ring and held there securely with wooden wedges. Miners work to better advantage when they have individual steels.

The practice of constructing a tunnel from just below the collar of the shaft to the sharpening-shop is to be commended. Such tunnels have a narrow-gauge track and push-car, and are lighted by electricity. By the use of them, drill-steel can be unloaded from the cage onto the push-car without disturbing operations around the surface of the shaft, which is always a busy place.

Recent improvements in mechanical drill-sharpeners and drill-makers, and the use of special dies for forming new-style bits, such as the Carr, have tended to systematize and improve the sharpening of drill-steel. The assiduous application of the principles of scientific management has indicated the immense importance of properly-designed and correctly-sharpened bits. Drill-steel and bits are seemingly trivial but actually are extremely significant matters. It is the drill-bit that is the critical link between the men and the rock to be removed.

The Copper in Michigan Ores

Sorting of the ore before hoisting is usual in the copper mines of Lake Superior. Just how much sorting to do is a nice point at this time of high prices for copper when the manager is given the choice either of hurrying out a lot of rich ore for the greater profit in its higher content of copper or of utilizing lower-grade ore that could not be mined in ordinary times. The *Houghton Mining Gazette* gives the present estimated amount of copper in pounds recovered by the Michigan mines per ton of ore treated as follows:

	Lb. copper per ton.		Lb. copper per ton.
Tamarack	19	South Lake	24
Osceola (old)	13	Arcadian	30–34
North Kearsarge	14	Isle Royale	15–15½
South Kearsarge	18	C. & H. (conglomerate)	23–25
Ahmeek	24	C. & H. (amygdaloid)	15–25*
Wolverine	20	Baltic	30–35
Mohawk	19	Champion	35–50
Franklin	20–21	Trimountain	24–26
Centennial	16½	Winona	18
Allouez	18	Victoria	14–16
Mass (including mass copper)	16–18	White Pine	35
Superior	18	Houghton Copper	28
Hancock	18–19	Lake	25
La Salle	12–13	Quincy	20–21

*Average perhaps 17.

It is to be noted that the mines of the Copper Range Consolidated show a high recovery, which is due partly to a good grade of ore and partly to unusually careful selection underground. The Quincy mine, which has been operated for more than 60 years, shows little variation in its grade of ore. The Franklin mine probably will increase its recovery, as more of the richer conglomerate ore is hoisted and less of the amygdaloid; this mine has bettered the grade of its ore gradually during recent years. Isle Royale has raised its recovery from 13 lb. a few months ago to 15 lb. at this time. The White Pine Extension, which has been diamond-drilling, and experimenting on the treatment of its ore, is planning its equipment, shaft-sinking, and buildings.

Chrysotile-Asbestos

By F. H. MASON

Playing the rôle of showman in the mineral section of a foreign pavilion at an international exposition brings forcefully to one's mind two things: what one does not know, or has forgotten, about minerals and what the other fellow does not know. The first, with a little diligence, can be remedied, but the polite answering of inane questions, day after day, is calculated either to send one irretrievably to perdition or fit one for the diplomatic service.

The asbestos exhibit in the Canadian pavilion seems to have appealed more than any other to the public fancy, and probably has been the source of more questions than all the other exhibits together. A number of people have taken objection to the classification, and if reminded that minium was at one time the name for red oxide of mercury, which, in times gone by, was so adulterated with peroxide of lead that the adulterant took the name of the article it was infringing, and that the same thing is taking place with asbestos and chrysotile, with the difference, however, that chrysotile is for most purposes the superior and far more expensive mineral, they are often inclined to sneer and pass on to the next case. Then there are not a few who have asked whether asbestos is a mineral or vegetable, and between these extremes have been a number of questions, some humorous, some perfectly intelligent, but the majority of which go to show that the public has many wrong notions about the mineral, the chief of which is that asbestos is the most fire-resistant substance known to science. It would seem, then, that, though I do not pretend to offer anything new on the subject, a short account of the mineral will not be without interest.

It is well, at once, to admit that mineralogically, chrysotile is not a true asbestos, but commercially, owing to the fineness, flexibility, and tensile strength of its fibre, it has almost entirely replaced asbestos proper for many purposes, and has a market-value twenty to sixty times greater than the latter mineral. Thus the man on the street, who, after all, plays no small part as an arbiter in the matter of language (I am prepared for squalls, Mr. Editor) has dropped the word 'chrysotile' and adopted 'asbestos' instead. Who, for instance, ever saw the curtain in front of the stage at a theatre labeled 'Fire-proof chrysotile curtain'? yet probably 90% of the so-called asbestos curtains are made of chrysotile.

The term 'asbestos' was originally applied to highly fibrous varieties of hornblende having a formula $RSiO_3$, in which R represents magnesia and lime, which, however, may be replaced by ferric or ferrous oxide, or alumina, and sometimes two or all of those oxides. Chrysotile, on the other hand, is a fibrous variety of serpentine having a formula $H_4Mg_3Si_2O_9$, a small part of the magnesia being sometimes replaced by ferric oxide and more rarely by ferrous oxide or alumina. It will be seen, then, that both varieties are silicates of the alkaline earths, chrysotile being more base than the hornblende variety, and, unlike the latter, contains some 13% of combined water. But it is in the physical, rather than the chemical, properties that the great difference between chrysotile and hornblende asbestos is found. The fibre of chrysotile possesses a far greater tensile strength and flexibility and can be separated into infinitely finer threads, and, for these reasons, is much better suited for weaving purposes. Chrysotile loses water at a dull-red heat, and, at the same time, loses much of its flexibility, then behaves more like the hornblende varieties; between 1200 and 1300°C. it sinters and breaks up into olivine and enstatite, and at 1700°C. it fuses. It will be seen, then, that while chrysotile resists heat to a marked degree, and, in the case of a fire-proof curtain, would confine effectively the fire to the side of the curtain on which it occurred—though it would lose its flexibility in the effort if the fire were a big one—it is by no means the most refractory substance known, and would be entirely unfitted to resist the prolonged attack of high temperatures, such as are to be found in many metallurgical operations. It is, perhaps, as a non-conductor of heat that chrysotile shows to the greatest advantage. The loose or woven fibre is crowded with myriads of minute air-cells, and, the fibre being incombustible, it forms an incomparable heat-insulator. Combined with magnesia and magnesium chloride or portland cement, it is used, and being used more and more, as a fire-proof material for the roofs and sides of buildings. Chrysotile rope, mixed with graphite for lubricating purposes, forms an excellent packing for stuffing-boxes that are heated by high-pressure hot water, steam, and hot air to such a degree as to put organic packing-materials out of the running. These are only a few of the many uses to which asbestos can be put advantageously.

Today, Canada is providing about 85% of the asbestos production of the world; all of this is chrysotile, and is obtained from the great serpentine belt in the eastern townships of the province of Quebec. Owing to the overburden in this neighborhood, much of which is heavily wooded, the limits of the belt have not been determined, but it is known to be over 6 miles long and 1¼ miles across in the widest part. The belt is crossed in all directions by granite intrusions that seem to have played a part in fissuring the serpentine, for it is generally near these intrusions that the most productive ground is found. Fritz Cirkel, from whose excellent work* I have borrowed extensively, has estimated the known produc-

*'Chrysotile-Asbestos: Its Occurrence, Exploitation, and Uses.'

tive area to be 11,320 acres, of which about only one-tenth is under active development. In the productive areas the fissures, whether caused by granite intrusions or by other means, cross the belt in all directions; they have been filled by chrysotile fibre, undoubtedly formed from the surrounding rock, which is of almost identical chemical composition. Except in slickensides, where the fibre lies parallel with the planes of movement, and is known as 'slip-fibre,' it always occurs at right angles to the dip of the veins. The 'slip-fibre,' besides chrysotile, often contains picrolite, which, on account of its inferior physical qualities, is separated as much as possible from the material that goes to the mill.

By far the greater quantity of chrysotile produced is won by quarrying in open pits, that rarely exceed a depth of over 250 ft., through chrysotile has been proved at depths of over 400 ft. The whole of the productive rock is removed, the long-fibre asbestos separated by hand-cobbing, and the rest of the material sent to the mill. Statistics over the last two years show that the fibre recovered forms only 6% of the material milled; the figures for 1913 being 2,110,990 tons milled and 127,539 tons of fibre produced.

A Trip Through Eastern Canada

By P. B. McDONALD

In spite of the War, the production of asbestos in the eastern townships of Quebec is larger than for several years. This district, from which comes the greater part of the world's supply of asbestos, had been depressed for a long time, and matters looked still worse when Germany's large consumption suddenly ceased. But the demand began to improve last winter, during which season, as a rule, the open-cut asbestos mines are closed, by reason of difficulties arising from snow and water. Companies that practically stopped work in the early days of the War have resumed operations and have been steadily increasing their production. The renewal of profit is due partly to the improved general outlook in the United States and Canada, and perhaps to the efforts being made by both British and American manufacturers to capture German trade in South America and other markets where asbestos products are in demand. Another consideration is that Russian export of asbestos has been hindered by the blocking of trade-routes, so

EXHIBIT OF ASBESTOS IN THE CANADIAN PAVILION OF THE PANAMA-PACIFIC EXPOSITION.

that competition is lessened. Incidentally the possibility of producing asbestos in Arizona is receiving attention.

Traveling on the Quebec Central railway, which runs between Sherbrooks and the city of Quebec, it is easy to tell when the asbestos country is reached, as a thick gray dust fills the air, covering the bushes and everything in sight. It is the result of the dry processes of concentration used in the big barn-like mills that are scattered among the pits. One is reminded of an oilfield by the many towers and tripods rising on the edges of the pits, where they serve for cable-hoisting systems, since they resemble derricks in the manner in which they dot the landscape. A visiting mining man is surprised to see this system of hoisting by a network of cables strung across the pits, usually radiating from one tower near the hoist-house, and each held at the other end, across the pit, by a separate fastening, near which is a little house where a boy signals by electric-button to the hoisting engineer. Thus a single pit, not so large as a Lake Superior iron-ore pit, but probably deeper, will have half a dozen cables strung across it, run by half-a-dozen hoisting-engines, each with an engineer and a signal-boy. It appears at first as though the hoisting could be concentrated, so that two or three hoists at a pit could be eliminated, and a Michigan iron-miner would ask why a single inclined track with a good-sized skip handled rapidly could not replace the half-dozen cable systems with their one-ton 'boxes.' A loaded box is raised vertically from the pit to the horizontal cable, then run to the dumping-station in the cable-tower. Once or twice Cornish mine-bosses have tried to concentrate the hoisting, but without success, because tram-cars and tracks are a bother in these narrow pits, by reason of irregularities caused by caving walls, and the blasting and sorting systems in vogue. The asbestos is found in jointed irregular ground with weak walls, so that drill-holes pointed in the 'toe' of a mass of rock and blasted will break a huge amount into the pit. Thus it is advantageous to have in the pit as little paraphernalia as possible.

The pit of the B. & A. Asbestos Co., at Robertsonville, one of the biggest asbestos mines in the world, has been hoisting nearly 1000 tons per double-shift. Thus with five hoists, raising one ton at a time, each hoisting-engine has a hundred loads to handle in ten hours. The asbestos-rock is taken in cars by gravity, to the mill, where it is crushed, concentrated, and packed. After preliminary crushing in a jaw-crusher, the material is dried. Since the concentrating is accomplished by dry or air methods, it is necessary that the crushed rock should be dry and dusty, so that the 'fibre' can be separated from the rock particles, to which they would adhere if damp. The drying is done in long, revolving, inclined cylinders, each containing five smaller cylinders or tubes, while a wood-fire underneath furnishes the heat. Each tube is a foot in diameter and serves to separate the material into lesser streams more readily affected by the heat. Wood is burned as fuel because of the longer flame and because the heat from coal is too intense. The use of coal is exceptional. After drying, the material goes through small jaw-crushers, is sized on shaking-screens, crushed again in mills that reduce the particles with revolving iron beaters, and is then screened and re-screened to separate the fibre from the tailing. On the shaking-screens, inclined at a small angle, a suction like that of a 'vacuum-cleaner' across the lower portion lifts the fibre, leaving the fragments of rock to go over the end. To separate the dust from the fibre, several large galvanized-iron revolving cones are employed, arranged with their tops opening through the roof of the mill, so that the dust may blow away. The product, which resembles matted silk or cotton fluff, is graded according to the length of the fibre at the different bins and packed into burlap bags for shipment. The longer the fibre, the higher the market-value; fibre two inches long and unusually silky (generally picked from the ore before going to the mill) brings several hundred dollars per ton, though there is not much of this. Such long fibre can be spun into asbestos cloth and special articles. One or two localities, notably around Thetford, produce most of the long fibre. The market-prices paid for asbestos vary from $10 to $275 per ton, different grades bringing $30, $50, or $100 per ton.

The proportion of fibre to the rock hoisted varies from 5 to 10%; in exceptional cases it is as high as 13 or 14%; usually a mine hoisting 1000 tons of rock per day will produce less than 100 tons of asbestos, perhaps 60 or 70 tons. Each mine accumulates an enormous waste-dump of fine crushed rock or tailing, built high by conveying the tailing up a long incline. These great waste-heaps are a striking feature of the district; added to the towers, cables, and the dusty atmosphere, they make a scene of industrialism that impresses the visitor. The features that will linger in his mind are the concentrating without water, the multiplicity of hoisting-cables, the texture and nature of the asbestos-rock, and the excellent labor available.

Asbestos is found over a large territory in Quebec. The fibre is mixed in a medium-hard gray rock, through which it is interspersed as stringers or veinlets; the rock lies nearly vertical, and the merchantable deposits may be several hundred feet wide. The fibre is locally called 'cotton.'

The labor-supply is excellent. The men are capable, sinewy, and not afraid of a day's work. The asbestos mines are in the heart of French Canada, where the contented and sturdy 'Canuck' is at home. It is not necessary to furnish these miners with 'welfare' advantages to keep them interested; they are full of the *joie de vivre* and of vigor, as is indicated by their large families. No happier people is to be found on the North American continent. Incidentally it is a striking example of British liberty to find the French schools in Quebec using French text-books instead of English, and the French communities are allowed all possible privileges in managing their own affairs. I enjoyed much pea-soup on my trip; and in asking my way along various roads was struck by the universal courtesy of *le habitant* and his bright-eyed progeny, who were always glad to supplement a limited knowledge of the American language by going out of the way to do a service. It is

interesting to see, so few hours from Boston or New York, an extensive country where 'Safety First' is spelled '*Sureté d'abord,*' the Post-Office is labelled '*Bureau de Poste,*' and where everyone from seven to seventy wishes you "*Bon jour, monsieur!*"

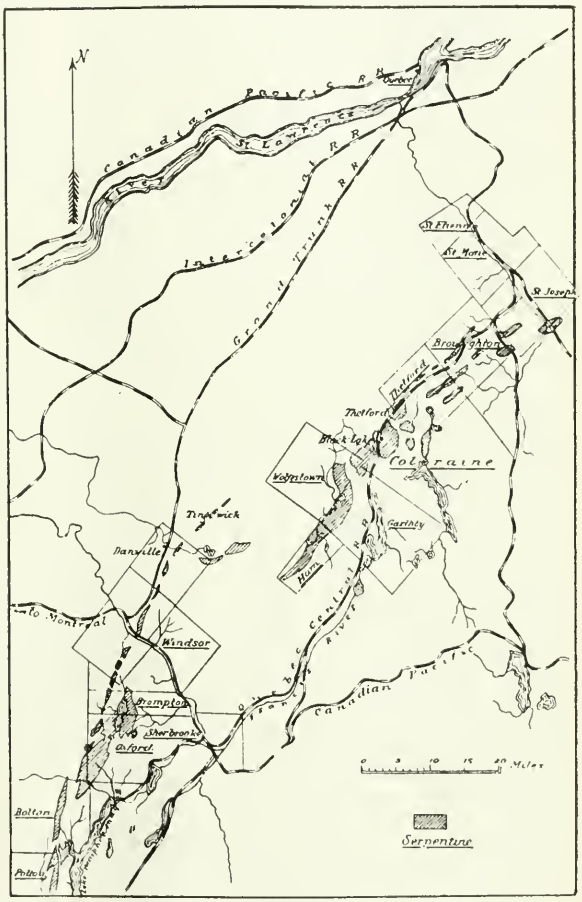
The asbestos industry has the reputation of being a business of small profits, owing to the competition of a number of companies. But this Canadian district is by far the most important in the world, and just now, at least, is doing well.

A few miles to the south of the asbestos country, near Weedon, is a profitable copper mine, the McDonald, named from the prospector who was responsible for its exploration, and who reaped a well-deserved reward in a financial way. Although only a small mine, as copper mines go, this property is shipping steadily, and is surprising people by its success. Sixty men are employed and close to 200 tons of ore daily is sent over an aerial cable-way to Weedon station, to be forwarded to smelters in 'the States.'

In Nova Scotia, the coal-mining industry was a little slack in 1914 and the customary 7,000,000 tons was not attained by over half a million. More optimism is apparent at present, because of opportunities for selling Nova Scotia coal in ports where Welsh and Scotch coal is not now available on account of Britain's extraordinary demand for war purposes. Nova Scotia's coal mines are especially valuable because most of them are situated on Cape Breton island, within a few miles of ocean-ports at Sydney and Louisburg. Twelve thousand men are employed in these mines, which are controlled by two or three large corporations; a number of slopes and shafts are in operation on several seams. The shipments to the United States, never very large, fell to considerably below the customary half-million tons in 1914. The iron and steel industry at Sydney, represented by the Dominion Iron & Steel Co., and the Nova Scotia Steel & Coal Co., with furnaces on tide-water, also was slack in 1914. Excellent iron ore is obtained from Bell island off the east coast of Newfoundland, being brought in steamers over the 400 miles of water. The two big iron-ore mines on Bell island, extending several miles under the ocean, have been gradually expanding operations since the dull times of the last autumn. The profitable German trade with the Krupps ended with the War, but the English demand has been growing.

Not so much is heard recently of the big new development planned for the sparsely-settled west coast of Newfoundland. A company with a capital of $8,000,000 promoted by 'Carbide' Wilson, has done extensive surveying and designing for water-power development, mining, milling, etc., at Bay of Islands; and negotiations with the Government have been in progress for privileges as to water-power, phosphate lands, sites, etc. The Reid family, of St. Johns, which built and operates the Newfoundland railway, is reported to be financially interested, together with Canadian capitalists. It is said that two thousand men will be employed. If successful, this will be the first large industry for Newfoundland's neglected west coast, the old 'French shore' of fishery disputes.

The difference between Canada's banking system and



SERPENTINE AREAS IN THE EASTERN PART OF QUEBEC.

that of the United States is apparent particularly in the method of assisting new business. A Canadian business-man of good reputation, who needs funds for carrying out his projects, will go to a bank and make a complete statement of his plans. The bank investigates his affairs thoroughly, and furnishes the capital necessary. Thus the banks uphold industries to an extent unheard of in the United States, and enter into a man's personal plans to such a degree that they are virtually partners in the several diverse businesses that usually grow up as their client's interests multiply.

Cyanide Treatment of Flotation Concentrate

By CHARLES BUTTERS and J. E. CLENNELL

When Charles Butters began to take up the work of flotation in our Oakland laboratory, one of the first points brought to our attention was the treatment of the concentrate produced by flotation; J. E. Clennell was accordingly instructed to undertake the researches detailed in the present paper.

The whole value of the process hinges on two points, namely, the grade of tailing produced and the net realization of the value contained in the concentrate, these two considerations being of equal importance. This last point is complicated by questions of geographical situation, for if the concentrate cannot be treated locally the cost of realization may be so heavy that flotation would be entirely precluded.

The results obtained in our laboratory by the combination of flotation and cyanide have been so remarkable that a serious study of the disposal of concentrates has been forced upon us.

The difficulties attending the treatment of concentrate by cyanide are well known. The process of concentration collects in a small bulk not only the valuable constituents of the ore but also those substances that act as cyanicides, or which are readily converted by oxidation or otherwise into cyanicides, so that their influence, per ton of material treated, is greater than would be the case with the unconcentrated ore. Heavy minerals such as the sulphides of iron, copper, lead, arsenic, antimony, zinc, and double sulphides such as mispickel, proustite, pyrargyrite, and bornite, naturally tend to accumulate in the concentrate. If some interval elapses between the formation of this concentrate and its treatment, oxidation may take place, with formation of sulphates, arseniates, and antimoniates, which are still more detrimental to cyanide treatment than the original minerals. These difficulties have been wholly or partly overcome by the adoption of modifications in the treatment, such as preliminary water, acid, or alkali washing, roasting, fine grinding, the use of special solvents, such as bromo-cyanide, and prolonged contact of the material with cyanide, extending in some cases to over a month.

In the case of concentrate produced by flotation, the minerals composing the product are substantially the same as those obtained by gravity concentration, consisting of the sulphides and double sulphides of the heavy metals, and it is to be expected that the same difficulties will be encountered in their treatment. But as the concentrate also contains a considerable part of the oil, tar, or other flotation agent, the presence of this foreign matter must be taken into account. In some cases, this circumstance introduces an additional difficulty. A part of this organic matter is soluble in the cyanide or alkali used in the process, and the solution so formed may be capable of absorbing oxygen. The effect produced by carbonaceous matter in precipitating gold and silver previously dissolved by cyanide is well known and has been a source of much trouble in many localities. Some of the constituents of this matter are not easily eliminated and appear to resist oxidation even at a high temperature; roasting under ordinary conditions does not completely remove the carbon; it is probable that a portion derived from tar remains in the graphitic form, capable of acting as a precipitant for gold or silver.

The experiments detailed below were made on concentrates produced from typical gold and silver ores by a modified type of the Minerals Separation flotation machine. Most of the tests were made in neutral or alkaline media. The frothing agents employed were those in general use, consisting of tar, creosote, carbolic acid, pine-oil, and fuel-oil. It is not proposed to discuss these in detail in the present paper; it will be sufficient to state that the concentrate was collected and drained on a vacuum-filter and in some cases dried at a moderate temperature before cyanide treatment.

As an example of an ore in which the value consists essentially of gold we may take the product of the San Sebastian mine, in Salvador, operated by the Butters Salvador Mines, Ltd. For preliminary work a composite sample was made from 21 lots taken from different parts of the mine, and concentrate produced by treating the finely crushed ore in a 10-lb. flotation machine. The sample taken for this test assayed originally 1.54 oz. gold and 0.28 oz. silver. The concentrate obtained by flotation assayed 4.92 oz. gold and 1.14 oz. silver. As this constituted 25% of the weight of ore taken, the gold recovered in the concentrate amounted to 79.9% of the total. An analysis of the concentrate showed:

	%		%
Insoluble	44.3	Iron	24.3
Sulphur	26.2	Copper	0.8

together with small quantities of molybdenum, tellurium, and other elements. The tailing carried 0.04 oz. gold per ton.

The first tests were made with the object of determining whether this material could be treated advantageously raw by agitation with cyanide. In addition to direct cyanide treatment various modifications were tried, as shown in Table I, including addition of lead acetate, preliminary alkali treatment, desulphurizing with alkali and aluminum, and bromo-cyanide. The last procedure showed a marked improvement over every other method of raw treatment, but still failed to yield a satisfactory extraction. The extraction was increased by increasing cyanide strength, but with strong solution the consumption of cyanide became prohibitive, and alka-

line sulphides were formed. This effect can be prevented and cyanide consumption much reduced by addition of lead acetate, some improvement in extraction being obtained. Preliminary alkali treatment with or without aluminum showed no benefit whatever. The fact that bromo-cyanide has a marked effect on the extraction suggests that a portion of the gold may be present as a telluride. This conclusion is supported by experiments made by direct treatment of the original ore, without concentration; these tests showed that a certain proportion of the gold is inaccessible to cyanide even after very fine grinding and prolonged contact. (See Table XI on page —.)

concentrate was cyanided raw before roasting and acid-washing, and re-cyanided after the washing; this also showed no advantage either in extraction or cyanide consumption over direct roasting, water-wash, and cyanide. In all cases the roasted material was agitated with cyanide, using a dilution of 3:1. The results obtained by these three methods are shown in the following table. (No. II.)

In Test No. 2 the acid-washing was made with 1% H_2SO_4, using approximately 5 tons of wash per ton of concentrate treated. Before agitation with cyanide, the pulp was re-ground in a model tube-mill with glass marbles.

8.	Similar to No. 7, but without bromo-cyanide	8	0.25	35.5	..	..	3.50	0.86	28.9	33.3

As these results did not appear encouraging for any system of raw treatment, attention was next turned to roasting. It was soon found that roasting within certain limits of temperature converted a considerable part of the copper into sulphate, which could be leached with water, together with some sulphate of iron, leaving the residue in a favorable condition for cyanide treatment. Preliminary acid wash of the roasted material was also tried; this would have the advantage of dissolving a further quantity of copper that might have become converted into oxide in the roasting, but the results show that the benefit obtained would not warrant the additional cost. Another test was made in which the concentrate was cyanided raw before roasting and acid-washing, and re-cyanided after the washing; this also showed no advantage either in extraction or cyanide consumption over direct roasting, water-wash, and cyanide. In all cases the roasted material was agitated with cyanide, using a dilution of 3:1. The results obtained by these three methods are shown in the following table. (No. II.)

In Test No. 3 the preliminary raw treatment was made with 0.1% KCN using a dilution of 2:1, for two days; the extraction of gold was 12%. Acid treatment was made with 1% H_2SO_4, dilution 1:1, agitated 18 hours and then leached with water before cyaniding. Roasted and washed concentrate agitated with cyanide for 4 days.

Test No. 1 on Table II indicates that the flotation concentrate from the San Sebastian ore may be successfully treated by a simple process of roasting, water-washing, and cyaniding. This conclusion was confirmed by numerous experiments on a larger scale in which the material was roasted in a hand-reverberatory furnace, and the

roasted product treated by agitation in tanks with mechanical stirrers, adding water, settling, and decanting until the bulk of the copper and iron salts was removed, finally collecting the material on a vacuum-filter and washing on the filter to remove the last traces of soluble salts. The washed concentrate was then repulped with lime and cyanide solution in an agitation-tank, and treatment continued in the ordinary way. The results of the bottle tests were fully confirmed.

Attempts to treat the material by percolation were not successful. Owing to the fine grinding of the ore previous to flotation, the roasted material showed a tendency to slime; percolation took place slowly and irregularly, through channels formed in the mass, so that the extraction by this means was always imperfect.

In the tests made in the large muffle the oxidation was somewhat more effective, but a rather longer time was required to reach the temperature at which roasting began. Temperature was approximately determined by Seger cones.

On examing the details of Table III, it will be apparent that the most favorable results were obtained when roasting was carried out at a low temperature; under these conditions a maximum amount of copper was extracted by water-washing, and the highest extraction of gold obtained with a minimum cyanide consumption.

TABLE III

BOTTLE-AGITATION TESTS ON CONCENTRATE ROASTED AT DIFFERENT TEMPERATURES

In each case 100 grams of concentrate was roasted in the muffle, and a test made of the roasted material, after water-washing. The charge for cyanide treatment was as follows:

Roasted and washed concentrate, 60 gm. Lime, 0.6 gm. Solution, 180 c.c. 0.5% KCN. Agitated at intervals for 3 or 4 days and solution strength maintained at 0.5% KCN.

	Gold, Oz.	Silver, Oz.

In this ore the silver is negligible, but it is significant that the silver extraction on the roasted material is poor in all cases. This condition will be noted in most cases where attempts have been made to treat silver ores by cyanide after an oxidizing roast.

With these results as a guide, tests were made on a larger scale on the same material, roasted by hand in an oil-fired reverberatory furnace. A charge of about 400 lb. was dried slowly in a sample drier, and charged into the furnace; the temperature was gradually raised till it approximated that obtained in the muffle-roasts, probably about 550° C. After 3½ hours, the flame was turned off and the charge allowed to cool in the furnace overnight. The concentrate roasted in this way, showed little or no tendency to sinter or form lumps, but in subsequent tests when the material was charged without previous drying, portions of the concentrate agglomerated into comparatively hard lumps, which contained a core of unroasted material, and which it was necessary to sift out and re-roast after grinding. Possibly in practice it would be advisable to pass the material, after drying and before roasting, through a ball-mill or similar pulverizer.

A bottle-test made on a scale of 100 gm. on a sample of roasted concentrate from the above reverberatory charge showed the following results:

TABLE IV

Copper extracted per cent of raw concentrate:	
By water-wash	0.435
By cyanide	0.039
Total	0.474
Cyanide consumed per ton of washed concentrate	5.03 lb.
Cyanide consumed per ton of raw concentrate	4.21 lb.
Under cyanide treatment	3 days

1 ton raw concentrate = 0.837 ton washed.

	Gold, Oz.	Silver, Oz.
Assay of roasted concentrate	3.70	0.86
Assay of washed concentrate	3.90	0.94
Assay of washed concentrate calculated on raw concentrate	3.26	0.79
Loss per ton of raw concentrate	0.24	0.10
Residue assay on washed concentrate	0.05	0.60
Residue assay calculated on raw concentrate	0.04	0.50
	%	%
Extraction on roasted and washed concentrate	98.7	36.2
Extraction calculated on raw concentrate	98.9	43.8
Recovery calculated on raw concentrate	92.0	32.6

The loss shown in this test seems to be mostly mechanical, due to dust carried off while stirring the charge; it could probably be much reduced by using a suitable roaster with revolving rabbles and a dust-chamber.

Agitation Tests

The following tests were made in small tanks fitted with wooden paddles.

No. 1. Agitated with cold water, washed by settlement and decantation, then drained by vacuum on a horizontal filter-tray; re-pulped with lime and cyanide solution.

No. 2. Agitated with hot water, washed by settlement and decantation, neutralized with lime and agitated with cyanide without previous filtration. Cyanide treatment by decantation, finally washing with water.

†In calculating 'recovery,' allowance is made for losses of gold and silver in roasting.

Percolation Tests

Portions of the same roasted charge as were used for the previous tests were leached in tanks with a canvas filter, using vacuum to aid filtration. After washing out soluble salts as far as possible in this way, the residue was mixed with lime and treated by percolation with cyanide solution in the same manner.

The result of these tests indicates that thorough washing is essential for a high extraction. Filtration without vacuum was found to be practically impossible.

The following tests were made on another portion of roasted concentrate, to determine the influence of cyanide strength on extraction. Eight tests were made; in the first four a preliminary wash was given with hot salt solution, 10% NaCl using 2 tons of material treated. In the remaining four tests the preliminary wash was given with water alone, using 4 tons per ton of material. The salt wash showed some extraction of silver, but it does not appear that any advantage derived from this would warrant the additional cost.

The cyanide treatment is detailed below.

TABLE VI

*See note, page ??

In view of the unsatisfactory results obtained by percolation and the fact that further extraction was made by increased water-washing, the residue of charge No. 1 was mixed with the residue of charge No. 1 treated by agitation (see Table V) and the united charge agitated further with water, then with weak cyanide solution and finally with water again.

8	0.411	0.038	0.449	0.062	3.44	2.79	0.10	0.72	0.08	0.58

Series No.	Test No.	Extraction on roasted and washed concentrate. Gold, %	Silver, %	Extraction calculated on raw concentrate. Gold, %	Silver, %	Recovery calculated on raw concentrate. Gold, %	Silver, %
1	1	98.4	23.2	98.5	53.4	94.4	13.4
	2	98.3	23.2	98.3	53.4	94.2	13.4
	3	98.3	25.6	98.3	55.4	94.2	15.2
	4	98.1	24.4	98.2	54.5	94.1	14.3
2	5	98.6	50.0	98.6	51.8	93.1	47.3
	6	98.6	48.5	98.6	50.9	93.1	46.4
	7	98.3	46.2	98.4	48.2	92.9	43.7
	8	98.2	45.5	98.4	48.2	92.8	43.7

From these results it appears that the extraction is scarcely affected by variation of cyanide strength within the limits and under the conditions of the tests. The cyanide consumption, however, increases with increasing strength. Apparently the best results are obtained with a strength of 0.125% KCN.

Two tests were also made on another portion of roasted concentrate from the same lot of ore to determine the influence of time on the cyanide treatment. The results are shown below.

From this test it is evident that the gold in the roasted concentrate is rapidly soluble in cyanide. The small insoluble portion seems to be quite inaccessible to prolonged treatment or to stronger solutions.

The foregoing tests sufficiently indicate that the San Sebastian concentrate, produced by flotation, may be treated successfully on a commercial basis by the method of roasting, water-washing, and cyaniding. Some tests were, however, made by alternative methods for the purpose of comparison.

	%	%	%	%
Residue of roasted and washed concentrate.....	97.9	39.8	98.0	43.9
Extraction calculated on roasted concentrate	97.9	35.1	98.0	39.6

The processes thus tried were:

1. Chlorination by saturating the roasted charge with chlorine gas and leaching with water, as in the old Plattner process.

2. Direct cyanide treatment of the raw ore after fine grinding in a tube-mill with steel balls.

Chlorination Tests

A charge of roasted concentrate was moistened with about 15% of water, and placed loosely, without any paper or other filter, in a porcelain funnel with flat perforated diaphragm. Chlorine gas was introduced from below through the neck of the funnel, and after saturation, the charge was allowed to stand covered for 24 hours. It was then leached out with water and the residue dried and assayed. The extraction was found by difference of head and tail assays; it was also checked by precipitating the filtrate with ferrous sulphate, allowing to settle and collecting the deposited gold on a filter. This was dried and cupelled.

In one case the residue after chlorination was further treated by agitation with cyanide. The results obtained by chlorination are detailed in the following table:

The residue from test No. 3 (Table X) was further treated by cyanide, by agitation for 4 days with a solution originally at 0.2% KCN, and increased toward the end of the treatment to 0.5% KCN, using a dilution of 3:1. This treatment yielded the following results:

	Gold, Oz.	Silver, Oz.
Final residue after cyanide treatment	0.07	0.87
	%	%
Extraction from chlorination tailing	41.7	19.4
Total extraction from raw concentrate	98.3	18.4

From these figures it would seem that the results to be expected from chlorination, or from chlorination followed by cyanide, are in no way superior to those obtainable by water-washing and cyanide. Either method will give a satisfactory extraction and the choice would depend on relative cost under local conditions.

Direct Cyaniding of Raw Ore

It is interesting to compare the results obtainable on this ore by direct cyaniding without any form of concentration, with those given by the combination of flotation and cyanide.

The following tests were made on portions of the same lot of ore as was used for tests detailed in the preceding tables. Three charges were treated; the first two were taken from a portion crushed in a small tube-mill with manganese-steel balls, using the following quantities:

Ore, 25 lb.; lime, 0.25 lb.; water, 17 lb.

Time of grinding, 6 hours.

The pulp was drained on vacuum-filter to 26.4% moisture.

The third test was made on part of a larger portion of ore crushed in the same manner, but in a larger mill, for use with a 200-lb. flotation machine.

The tailing thus produced was agitated with cyanide, with results as shown below.

TABLE XII

Cyanide Treatment of Raw Flotation Tailing
Wet weight of tailing taken, 100 gm.
Moisture, 7.4%. Dry weight, 92.6 gm.
Lime added, 1 gm. = 21.6 lb. per ton of tailing.
Strength of solution maintained at 0.2% KCN.
Dilution of final pulp, 3:1.
Time under cyanide treatment, 3 days.
Cyanide consumed per ton of tailing, 1.40 lb.

	Gold, Oz.
Assay before cyaniding	0.055
Assay after cyaniding	0.0125
Extraction	77.3%

Comparison of Methods

For the sake of comparison, we may assume in view of previous results that an extraction of 98% could be obtained from the concentrate yielded by the above flotation test, by the method detailed, namely, roasting, water-washing, and cyaniding. The values shown in the middling may be eliminated on the assumption that in practice the middling would be constantly returned to the head of the machine, and that finally only two products would be obtained, concentrate and tailing, having the same assay-values as in the test. The result of the flotation test would then appear as follows:

		Assay-value.		Per cent of total value.	
	Weight,	Gold,	Silver,	Gold,	Silver,
Product.	%	Oz.	Oz.	%	%
Concentrate ...12.97		6.53	1.04	94.6	103.8
Tailing 87.03		0.055	...	5.4	....

We have, therefore, per ton of raw ore:	Gold, Oz.	Gold.	Per-centage of total gold.
Recovered from concentrate: $6.53 \times 0.1297 \times 0.98$ =	0.830	$17.16	92.7
Recovered from tailing: $0.055 \times 0.8703 \times 0.773$ =	0.037	0.76	4.1
Total recovery	0.867	$17.92	96.8
Heads	0.895	18.54	100

Taking the figure of Test No. 3 (Table XI) as indicating the possible recovery by direct cyanide treatment we have:

	Gold, Oz.	Gold,	Percentage of total gold.
By direct cyaniding.....	0.74	$15.30	82.7
Additional recovery by combined method	0.127	2.62	14.1

	Per ton of concentrate.
Flotation, 16c. per ton of ore $= \frac{0.16 \times 100}{13}$ =	$1.25
Roasting	1.00
Extra labor, etc., in cyaniding	0.50
	$2.75
Per ton of raw ore, 2.75×0.1297 ..... =	0.36
Net saving by combined method.....	2.26

In addition to this there is a saving in cyanide consumption as follows, per ton of raw ore:

	Cyanide consumed.
By direct treatment	4.76 lb.
By combined treatment:	
Concentrate (say, 5 lb. per ton) 5×0.13 ..... =	0.65 lb.
Tailing, 1.4×0.87 ..... =	1.12
	1.77

showing a saving in cyanide of 2.99 lb.; taking cyanide at 16c. per lb. of KCN equivalent, this would amount to 48c. per ton of raw ore treated, bringing the total saving to $2.74 or about $9600 on a monthly output of 3500 tons.

The tests given in Table No. III show that about 0.4% of copper, or 8 lb. per ton of raw concentrate (in this case 2 lb. per ton of raw ore) can be extracted in a soluble form, and might be recovered as an additional source of revenue.

Safety-first apparently is reducing the number of accidents in the Michigan copper mines, according to the report of the mine inspector for Houghton county, Thomas James, for the year ended September 30, 1915. The fatalities totaled 34, in the following mines: Quincy, 7; Champion, 3; Trimountain, 2; Baltic, 4; Hecla branch, 7; South Hecla branch, 2; Calumet, 2; Red Jacket shaft, 3; Isle Royale, 1; Superior, 1; Centennial, 1; and Hecla Amygdaloid, 1. From October 1914 to September 1915, inclusive, the monthly totals were 1, 3, 1, 3, 2, 6, 7, 4, 2, 2, 2, and 1, respectively.

Records since 1910 are as follows:

Year.	Men employed.	Fatalities.	%
1910	16,250	58	0.0036
1911	15,361	51	0.0033
1912	15,554	36	0.0023
1913	13,813	32	0.0023
1914	12,954	29	0.0022
1915	16,005	34	0.0021

Water consumption at mines at Kalgoorlie, Western Australia, is as follows: Five plants treating a total of 69,942 tons of ore per month by the dry process used 202 gal. per ton; while four plants treating a total of 73,981 tons by the wet method consumed 190 gal. per ton. This water costs from 36c. to $1.68 per 1000 gal. The consumption includes everything from drinking water to that used in the power-plants at the mines and mills, and for sluicing away the residue. Water is also used for spraying tailing-dumps. All of the fresh water is supplied from a reservoir 353 miles distant, pumped through 30-in. pipes.

Pumping at the Commonwealth Mine, Arizona

By EDGAR A. COLLINS*

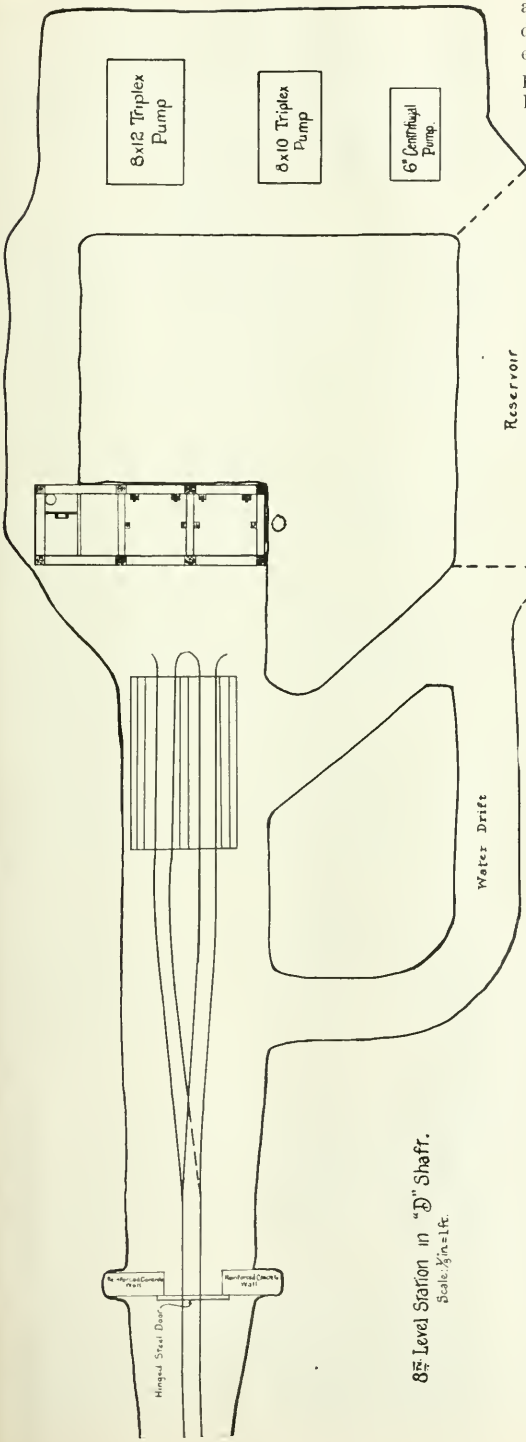
The main or D shaft of the Commonwealth mine is a 60° incline, sunk in the foot-wall parallel with the main vein and distant 100 to 150 ft. from it. The water-level is reached at an inclined depth of 425 ft. or 370 ft. vertically below the collar of the shaft. Former workings below the water-level, while of limited extent, had shown that a large quantity of water would be encountered when greater depth was attained. The vein is a fractured zone that offers a good channel for surface waters. The foot-wall andesite, on the contrary, is softer and close-grained, so that it does not contain much water. This was one of the principal reasons for placing the shaft in the foot-wall and parallel with the vein.

Sinking below the water-level was started in May 1914. The flow of water increased steadily until, at a depth of 485 ft., a fissure was encountered the flow from which taxed the capacity of the two No. 9-B Cameron sinkers. These pumps raised the water to the 7th level (410 ft.), so that their joint capacity was 500 to 600 gallons per minute when working at full speed. On this basis the flow was estimated at 500 gallons per minute. It was the original intention to cut the station for the 8th level at a depth of 510 ft., but after pumping steadily from the sump for two weeks without gaining on the water appreciably, it was decided to cut the station at 485 ft. and install the pumps while the sinkers were able to handle the flow of water. Before starting excavation for a station, the bottom of the shaft was cleaned and all holes and water-fissures plugged and wedged as tightly as possible. This reduced the flow appreciably.

In order to avoid draining the main water-fissure, which dipped into the shaft from the hanging wall at a flat angle, the pump-chamber was 'cut-under,' or in the foot-wall of the shaft. Contrary to expectation, the cross-cut to the vein did not develop any additional flow of water for the first 50 ft. or so, the ground being firm and fairly free from cracks. A suitable place was selected for a bulkhead and, as soon as possible, a steel hinged-door was set in the cross-cut to hold back the water in case of emergency. This door was hung from reinforced-concrete pillars set in the side of the cross-cut. A sketch of this door is shown herewith. It was designed by Otto Wartenweiler, mechanical engineer, of Los Angeles, and proved entirely satisfactory. Provision was made to reduce the water behind the door when it was shut by two valves, and the leakage was easily handled by one of the air-operated sinker-pumps that are kept ready for emergency. This door has been used repeatedly on occasions when electrical power was shut off for sundry repairs at the power-house and has regulated a flow of over 1300 gallons per minute with no trouble whatever. Without a similar bulkhead the pumps would have been flooded on several occasions.

Previous work below water-level, by the old company ten years ago, while not extensive, indicated the probability of a maximum flow of approximately 1000 gal. per minute, and that the normal flow would be consider-

*Manager of the Commonwealth mine.



ably less than 750 gal. per min. On this basis it was decided to install two separate units of 750 gal. per min. each. It was realized that the motor-driven centrifugal pump would be cheaper in first cost and would occupy less room with a little higher consumption of power, but the question of reliability of operation and general efficiency seemed to favor the plunger-pump of the triplex type. It was, therefore, decided to provide one unit consisting of two triplex plunger-pumps (one of which was already on the ground) and a second unit consisting of a 6-inch four-stage centrifugal pump with a rated capacity of 850 gal. per min. Therefore, specifications were sent to various manufacturers asking for quotations and efficiency guarantees, and after careful consideration the following equipment was selected:

One 8 by 12 Aldrich triplex pump, capacity 450 gal. per min., driven by double helical gears and direct connected to a General Electric motor of 75 hp. and 514 r.p.m. Weight, 25,500 lb.; price, delivered, $3264.

One 6-inch four-stage Alberger type S-turbine centrifugal pump with bronze impeller and diffusion-vanes, direct-connected with flexible coupling to a 150-hp. General Electric induction motor. Weight, 7835 lb.; price, delivered, $2128.

The Alberger Pump & Condenser Co. guaranteed a pump-efficiency of 70% and an over-all efficiency of 64.2%. No accurate efficiency-tests have been made, but it is believed that the results will closely approach this guarantee.

All three pumps have given satisfactory service. This is particularly the case with the centrifugal pump, which has been in practically continuous operation since it was started. A little trouble was experienced in starting the pump owing to faulty lubrication in the thrust-bearing, which is of the marine type. With the exception of the first month, however, this pump has only been shut-down when power was lacking. For the first two or three months it was possible to shut-down one or other of the plunger-pumps for short intervals. During the last six months, however, they have been steadily in operation and, except when power was lacking, have been shut-down only for short intervals to overhaul valves, etc.

About 667 cubic yards of rock was excavated for the pump-station and reservoir at a cost of $8.57 per cu. yd. The total cost of the entire station and equipment, including the extra electric wiring necessary, piping in the pump-chamber, steel bulkhead-door, etc., was $13,729, of which $8344.75 was the cost of the pumps and $3645.61 was paid for labor, as shown by the following table:

PUMP CHAMBER AND EQUIPMENT.

Labor	$ 3,645.61
Piping	800.06
Wiring	341.76
Steel bulkhead	186.62
Pumps	8,344.75
Miscellaneous	410.22
Total	$13,729.02

Actual pumping operations with the new equipment commenced in September, but regular records were not kept until the following month. At that time and at intervals since then weir-measurements have been taken of the quantity of water flowing to the sump. Checks were also taken of the amount delivered at surface by the different pumps. These were rough measurements and can be considered only as approximately correct. Readings of the current for the pump-motors have been taken from time to time; these show little variation in consumption of power. From the measurements the following pump-duties have been figured.

	Gallons per minute.	Power-consumption.
8 by 12 Aldrich triplex	440	70
8 by 10 Aldrich triplex	350	62
6-in. Alberger centrifugal	740	133

During the last six months a total of 383,277,000 gallons of water has been pumped to surface, equal to a daily average of 2,000,000 gal., at an average cost of 4.4c. per thousand gallons. The various items of this expense are shown in the following table.

DETAILED PUMPING COST, 6 MONTHS, MARCH TO AUGUST 1915, INCLUSIVE

Total water pumped, 382,277,000 gallons.

	Total.	Cost per 1000 gal.
Labor	$ 2,611.09	$0.0069
Supplies	801.37	0.0021
Electric power	13,158.00	0.0344
Compressed air	374.81	0.0010
Total	$16,945.27	$0.0444

Power is supplied from the company's steam-driven engine-generator plant and the average cost, including all renewals, maintenance of boiler plant, etc., was 0.016c. per kw-hr. or $8.57 per hp. month. In this connection it is fair to state that the power-plant is overloaded considerably at present and the condenser is unable to maintain a high vacuum. For this reason the cost of power is above normal during the summer months.

An interesting development of the pumping program has been the recent unwatering and recovery of a duplex plunger triple-expansion Dow steam pump at the 8th level of the old B-shaft. This pump has been under water for ten years, but was found to be in excellent condition. With the exception of a thin coating of rust on the outside, the pump was practically uninjured by its long stay under water. This is, of course, mainly due to the fact that the mine-water is unusually pure and slightly alkaline. As a matter of fact, it provides the domestic supply for the town of Pearce. This pump has since been overhauled, cleaned, and tested, and is now ready to serve as part of a duplicate unit for the old or C-shaft which is being sunk to the 10th or 570-ft. level. It is an efficient and economical pump, but as an illustration of the development of modern pumping practice it contrasts sharply with the electrically-driven centrifugal pumps, which will form part of the same unit, and which handle an equal quantity of water while occupying only one-twentieth of the space.

CHILE has an area of 292,100 square miles, which is well above that of the state of Texas, and a population of 5,000,000, which is greater than that of California, Oregon, and Washington combined, while Santiago, the capital of Chile, has 500,000. With an average breadth of only a little over 100 miles, it has nearly 3000 miles of coast backed for its entire length by the lofty and unassailable rampart of the Andes. The southern part is heavily wooded, while the north is an arid upland plateau containing important mineral products, nitrates, copper, and iron ore. The Chilean government has never yet passed a payment on its bonds, and it subsidizes a line of steamships plying between its own ports and as far north as the Isthmus of Panama. To an extent unusual in South America, the settlement of the country has been practically homogeneous; the European element composes the governing and wealthy class, and forms the backbone of the nation; this is a point of tremendous importance in the future development of the country. The Chile Copper Co., owning the Chuquicamata mines, is aiming at a production of 120,000,000 lb. of copper per year by its first unit of 10,000 tons of ore, daily capacity, at a cost of 6 cents per pound. Shipment of iron ore from the Bethlehem Steel Co.'s Tofo mines has been increased in the last year from 20,000 tons to 40,000 tons per month; an aerial tramway transports the output of the mines five miles to the coast. Iron and steel manufactures, electrical and mining machinery, form important shipments from the United States to Chile.

LIMESTONE SAND is being used for concreting the Sacramento shaft of the Copper Queen mine, Arizona. Tests show that this material makes a stronger concrete than ordinary quartz sand.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

GOGGLES should be worn by men using emery wheels; and safety-collars should be fitted to the wheels to prevent them from bursting.

THE STATIONS where telephones and first-aid apparatus are placed in mines should be marked by distinctive lights, as is done with powder-magazines.

COST OF LIGHTS in mines is as follows: oil torch, 6 to 10c.; oil safety-lamp, 7 to 9c.; electric lamp, 12 to 17c. per week. Belgian coal mines use the electric lamp extensively.

DREDGING AND HYDRAULICKING in the state of Victoria, Australia, has yielded a total of 1,004,034 oz. gold, from 219,851,948 cu. yd. since 1900. The average was 4.4c. per yard. During this work there was 650 tons of tin saved.

GALVANIZED-WIRE ROPE cannot be safely employed for hoisting or haulage work. The constant bending over sheaves or drums causes the zinc to scale off, leaving the rope in bad condition. Such ropes can be used for guys and similar purposes.

WHERE large square timbers are not available for head-frames or other heavy purposes, satisfactory timbers may be built by spiking boards or planks together. If the timber is to be framed, care must be taken that no nails or spikes are driven where mortises are to be cut.

TO ASCERTAIN the distance a body will fall (theoretically) during a given time, square the number of seconds and multiply by 16.08 ft., the distance through which the body falls during the first second. To fall 5000 ft. requires about 18 sec. The practical effect of the resistance of the atmosphere varies with the form and specific gravity of the falling object.

GALENA is nearly twice as heavy as pyrite. On the other hand zinc-blende and pyrite are so nearly identical in specific gravity that the practical separating of them by concentration is much complicated. One of the great troubles at Broken Hill was the separation of the blende and rhodonite; but flotation, as evolved there, solved the difficulty.

ELECTRIC PRODUCTION of iron is making rapid progress in Sweden, a country of large water-power development. There are 11 furnaces in operation, from that of 2500 hp. at Trollhätten to 10,000 hp. at Domnarfvet. Kilowatt-hours consumed at the Trollhätten furnace per ton of pig-iron are 2116; iron produced per horse-power year, 3.05 tons; and consumption of electrodes, 4.14 kilograms per ton of iron.

NATIVE SILVER found in the copper mines of the Lake Superior region for many years belonged, by custom, to the miners discovering it, if they were working by leasing. Now, of course, all valuable minerals go to the company.

DOLOMITE, a magnesian limestone, is being successfully substituted in basic open-hearth furnaces for magnesite, on account of the scarcity of the latter. When it is doubly burned, to thoroughly gasify it, it is found to be a good substitute. One disadvantage is its tendency to slake if a furnace is shut-down for a little time.

THE RELATION between kilovolt-ampere and kilowatt may be expressed as follows: kva. multiplied by power-factor equals kw. For example, in alternating-current practice, if voltmeters and ammeters are used to measure the potential and current, the product of voltage by amperage by 1000 equals the number of kva. being carried on the line. This, however, does not represent the work done unless current and potential are in phase, when current flows against resistance only, there is no inductance, and the power-factor is 100%. If there be a lag or lead of the current with respect to the potential, the two are not in phase, and the work done is not represented by the afore-mentioned product, but a further multiplier must be introduced, namely, power-factor, in order to find the work done. Suppose the potential and current measured are found to be 2200 volts and 113 plus amperes, then the kva. is 250. This is not the work done if the power-factor is, let us assume, 80%; the work done is then 250-kva. times 0.80, or 200 kilowatts.

MINERS of the Joplin district, Missouri, and their families are practically all of American stock. Many of them are only one or two generations removed from the Tennessee mountains and the Arkansas farming country, and as they drift into mining work are most often fresh from Missouri farms. These people are intelligent, independent, and industrious; as a rule they marry young, and large families are frequent, according to A. J. Lanza, of the U. S. Bureau of Mines. Their efficiency, as far as labor in the mines is concerned, is high, and probably not exceeded in any other mining community in this country. Many of them prosper in mining, and it is a common saying in south-western Missouri that every miner is a prospective operator. Although the sanitary environment of their homes often leaves much to be desired as regards its bearing on public health, the faults are essentially due to a lack of knowledge of the effect of certain practices. The men receive good wages. It is probable that sanitary education would not only be well received in the communities in the Joplin district, but would work a great deal of good.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

General Conditions During October.—Prices for Zinc, Lead, and Pyrite.—District Outputs.—New Work.

Ideal weather prevailed in the zinc region during October, resulting in an output of nearly 50,000,000 lb. of concentrate, the greatest in the history of this field. Heavy buying by eastern smelters unloaded the bulk of the reserve product found here at the beginning of the month, in a quarter heretofore inconsiderably engaged in the field, leaving the regular buying interests to pursue their usual vocation without much competition. Capital from new and unexpected sources flowed in. Building operations were favored by the good weather and mild temperature. In conjunction with State and local authorities, the more prominent mining corporations did substantial road construction, and macadam roads will soon be completed. The personal comfort of miners was not overlooked, several of the companies providing commodious modern change-houses, and numbers of cottages were built for miners at low rent. In some districts not a foot of land is now available for leasing, and scores of drill-rigs are working night and day.

In the first two weeks of the month, ore-buyers exercised caution in submitting offerings which had receded from above $80 per ton for 60% concentrate, to a range on which sales were being made from $70 to $75 per ton. Buyers representing the smaller smelter interests were restricted in their activities under instructions from headquarters, compelling bids on products above 55% zinc and on a base of $70 per ton. Under the circumstances the larger smelters, such as the New Jersey Zinc Co., Matthiesen & Hegeler Zinc Co., and Illinois Zinc Co., secured the bulk of the higher-grade offerings. Then came the turn as abrupt as pleasing: the smaller concerns began to set the pace, giving proof that the larger buyers referred to were paying advanced prices, and quotations cleared $10 per ton at one rise, bringing the price for top grades to $85 per ton. This quote held at the close of the month at a par with the prices that usually obtain in the Joplin field, but unlike the Joplin markets, remained stationary. Miners all over the field expressed their views that they were not getting a price for their product commensurate, or even nearly so, with the selling price of high-grade spelter, and there were peristent rumors of determined efforts to secure more satisfactory prices, or refuse to sell their products. More high-grade zinc ore was cleared from the Wisconsin field during October than ever before. The reserve, which amounted to several thousand tons at the beginning of the month, was entirely eliminated.

Lead-ore producers made substantial gains also. Efforts on the part of large smelters to stimulate buying failed, but a much improved tone became apparent at the end of October. Pig-lead rose to about $4.85 per 100 lb. Lead-ore producers found a better demand, but expecting higher prices, decided to hold their product. Sales were large at the close of the month, and more lead ore went to market than for any single month this year. The remainder is held, $55 per ton not being regarded as a satisfactory offering.

Pyrite held at stagnant figures, bringing about $3.75 to $4 per ton, on a basis of about 12c. per unit, the bulk of ore sold coming from the separating-plants, and containing 35% sulphur.

Carbonate-ore producers unloaded some finished product with the Lanyon Zinc Co. Missouri calamine quotations govern this product in Wisconsin and while $65 per ton was reported at intervals in the former State for 40% ore, the best that Wisconsin miners could do was $35 per ton for ore assaying about 35% zinc. The New Jersey Zinc Co. started a cleaning-up program on its holdings in the field, seemingly doing better on old dumps, gutters, and waste-heaps, than it accomplished with a large force of miners working underground. Much ore was left in the hands of small operators at the close of the month.

Deliveries of products in October were as follows:

District.	Zinc pounds.	Lead pounds.	Pyrite pounds.
Benton	14,388,000	330,100	.....
Mifflin	7,718,000	326,000	.....
Cuba	5,934,000	.....	2,267,056
Hazel Green	5,112,000	86,400	.....
Galena	4,446,000	.....	.....
Platteville	4,678,000	104,130	.....
Linden	3,274,000	149,650	.....
Shullsburg	1,380,000	.....	.....
Highland	738,000	.....	.....
Potosi	134,000	50,000	.....
Mineral Point	108,000	.....	.....
Dodgeville	.....	204,000	.....
Totals	47,910,000	1,250,280	2,267,056

The gross production of crude concentrates was about the same as reported in the deliveries; net refined ores direct to smelter, and concentrate out of the field, were 26,000,000 lb. The Mineral Point Zinc Co. followed a strenuous ore-dressing campaign, and shipped 2320 tons of high-grade separator product to the Nassau works, at DePue, Illinois.

Several new producers commenced; 10 new plants are rapidly nearing completion; two new separating-plants were started, and one will be put in commission during November; the acid-works connected with the plant of the New Jersey Zinc Co. at Mineral Point goes into service on November 15; rich discoveries of ore were numerous; and the drilling program is tremendous.

BOSTON

Report on Alaska Gold Mines Property.

Regarding the Alaska Gold Mines property, D. C. Jackling, the managing director, has issued the following statement:

"We shall not be able to achieve the expected results as soon as we had anticipated. We have encountered an unlooked-for intrusion of low-grade schist on the 5th level, from which point we had expected to draw high-grade material with which to sweeten up the known lower-grade ores, as we mined them near the surface. Notwithstanding thousands of drill-hole tests, we strangely enough did not cut into this low-grade intrusion. It will take us three or four months to get this material out of the way, and put the mine in shape to supply average ore to the full capacity of the mill. It is the inevitable disappointment which accompanies the development of a large property.

"For a time we were puzzled to know what had happened. Two stopes on the 5th level had run into something which completely upset our calculations. As soon as we ascertained the real status of affairs, we knew we would be delayed in open-

ing-up stoping ground of the desired average grade to feed 8000 to 10,000 tons daily to the concentrator. For some little time we shall continue to show smaller returns than anticipated.

"Up to the end of October we had treated in our new plant about 900,000 tons of ore, assaying about $1.25 per ton instead of the expected $1.75 per ton. We are now mining and milling for 60c. per ton, and have got our tailings losses down to 20c. per ton. These figures compare with an estimated cost of 75c. per ton and tailings losses of 25 cents, so that in increased operating economies we have an offset of 20c. per ton against the temporary low average ore yield. Including the 400,000 tons milled in the old plant, the average net assay value to date is brought up to $1.30 per ton.

"I might mention that never before in the history of mining has ore been mined from underground workings, hauled under ground a distance of two miles, hauled again to the mill, a distance of over two miles more, and put through a concentrator for a total cost of only 60c. per ton.

"Just now we are treating 5000 tons of ore per day. I think we will raise the tonnage next month to 6000; by the first of the year to 7000, and soon thereafter to 8000 tons. The next 2000-ton increase will come more slowly by reason of the delays already explained. Our milling plant is a marvel; it is more than meeting our expectations. It is the most efficient plant of its kind in existence, and we have more ore than can be mined out in a generation.

"There are always to be found timid souls who seem unable to stand up and face discouragements and annoyances which mining men accept as part of their business. When we were opening up the Utah Copper property, we were informed from the outside that our ore was too low in copper tenor to permit of a profit. All sorts of dire predictions were kindly sent to us. At Ray Consolidated and Chino also it was said we had run up against insurmountable problems. But we worked out of them all, until today at all of our properties we are milling no less than 21,000,000 tons of ore a year. Every one of these companies has money in the bank, is paying good dividends and does not owe a dollar.

"Alaska will prove all that was ever claimed for it, but we will be delayed a little in 'getting there;' that is the situation in a nutshell."

A broker's circular contains the following:

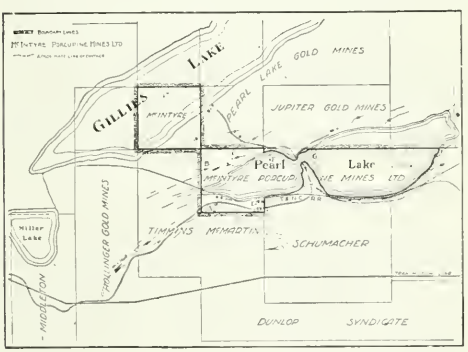
At the Alaska Gastineau company's mine eight stopes have been finished and are in actual stoping condition, five are in process of being prepared, and two more are being developed. Altogether there are now about 1,000,000 tons of broken ore in the mine. Ore has been delivered at the rate of 5500 tons per day, and this is now being raised to 7000 tons. The mine will easily be able to furnish ore to the full capacity of the mill by the first of the year. The Sheep Creek railroad is proving capable of handling 20,000 tons of ore per day. In the milling division the coarse and fine-crushing plants are now practically completed, and are able to treat easily up to 10,000 tons of ore per day. In the concentrating department the two units have shown a capacity in excess of 2500 tons each. Tailing is less than 20c., and should eventually, be not over 17c. The ratio of concentration has been increased from 350-1 to 750-1. The permanent re-treatment plant and the refinery are now ready. In the power division the Salmon Creek dam continues full and overflowing, and this plant is able to deliver all the power required for present operations. At the Annex Creek scheme, where additional power is being developed to care for the excess capacity of the mill, the plant should be in operation before the first of the year, so that after that date there will be power sufficient to treat all the ore that the mine and mill can handle. In the seven months that the property has been operating, the tonnage furnished by the mine and treated by the mill has increased rapidly for a new enterprise. Starting in March with 40,000 tons, the quantity has increased month by month, until in September there was approximately 132,000 tons treated. The average so far has been $1.50 per ton, with costs of 65c. per ton.

TORONTO, ONTARIO

Porcupine Mines: the Dome, Hollinger, Schumacher, and McIntyre.—Swastika, Kirkland Lake, Boston Creek, and Le Pas Districts.

The Dome company at Porcupine beat all previous outputs during October, with a production of $150,500 from 28,750 tons averaging $5.24 per ton, compared with $4.83 in September. ——The Hollinger also showed an increased return during the four weeks ending October 7. The gross profit was $158,342 from the treatment of 27,029 tons assaying $9.66 per ton; the working cost was $3.19 per ton. In addition to its own ore the Hollinger mill treated 10,990 tons from the Acme mine.—— The Schumacher has been added to the list of Porcupine producers, the yield during October approximating $20,000.—— Shareholders of the McIntyre company ratified the agreement made by the directors for the purchase of the Jupiter, which will accordingly be operated in connection with the McIntyre and Pearl Lake mines.

The directors of the Lucky Cross in the Swastika district,



THE MCINTYRE-JUPITER-PEARL LAKE AREA, PORCUPINE.

which is controlled by Philadelphians, have been inspecting the mine. It has been closed down for two years, and they propose to resume operations as soon as finances can be arranged.——In the Goodfish Lake area of the Kirkland Lake district, the La Belle Kirkland mine promises to become an active producer. A 25-ft. vein, which only showed traces of gold at the surface, is yielding high-grade ore at 100-ft. depth, where it has been opened for 100 ft. Five promising veins varying from 5 to 25 ft. wide have been cut. A compressor and hoist will shortly be installed.——The Beaver Consolidated of Cobalt, following the example of many other silver-mining companies, is getting interested in the gold areas, and has purchased 10 claims belonging to the Kirkland Lake Gold Mines.

A Detroit syndicate, represented by George C. Miller, general manager of the Miracle mine at Porcupine, has purchased control of a claim belonging to Fred. Connell and J. McDonough in Pecand township, near Boston creek. It shows ore of such richness that the owners have an armed guard in charge, having in view the wholesale and unscrupulous manner in which the King Dodds mine at Kowkash was plundered.

A good deal of attention is being directed to the Le Pas mineral area in northern Manitoba, situated some 74 miles north of Le Pas, and extending about 125 miles from near the western boundary of the province east toward James bay. The mineralized belt is about 50 miles wide, of Huronian formation, being largely conglomerate and Keewatin schist.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

Grading for the Alaska-Juneau mill is nearly finished; excavation follows. The mill-site is very steep. A great deal of lumber is being unloaded at the mill dock.

If $75,000 can be raised, and permission granted by the Department of War, a bridge is to be constructed across the Gastineau channel, connecting Juneau and Thane with Douglas and Treadwell. The strait is about two miles wide.

Orders have been placed this week by the Bradley, Bruff & Labarthe of San Francisco for a quantity of the equipment for the new Alaska-Juneau mill. Detailed information as to the successful bidders will be published in next week's issue. In the meantime it is of general interest to know that the grading for the coarse-crushing section of the mill will be completed on the 20th. The excavations for the main section of the mill proper, with the power-plant, and auxiliaries, are being pushed to completion rapidly, and it is expected that the pouring of concrete will be commenced within 30 days. This is the most important mill construction work that has been undertaken for a long while, and will include many innovations in what has been recognized for some time as standard mill-practice.

KETCHIKAN

(Special Correspondence.)—During the last two months 1200 tons of 3½% copper ore has been shipped from the Mt. Andrew mine; about 600 tons more has been mined and is waiting transportation to the smelters. Preparations are being made for shipping at Big harbor. A tram is being built from the lower workings to the harbor, a distance of about 1700 ft. The ore is medium-grade copper containing some gold. This mine has been developed to a considerable extent during the last 2 years.

The Rogers mine near Hollis has recently been opened to a depth of 350 ft. The ore-shoot is said to be about the same in both width and value as it was in the upper workings. Considerable driving has also been done, resulting in cutting another ore-shoot. The ore mined during development has been treated in the 5-stamp mill on the property.

Ketchikan, October 25.

ARIZONA

COCHISE COUNTY

The Copper Queen company has developed a large quantity of 3% ore in its Sacramento hill, and to treat this a mill with two 1500-ton units is to be erected. Preliminary work will soon commence.

GILA COUNTY

During the quarter ended September 30 the Magma Copper Co. produced 1,973,960 lb. copper at 5.72c. per pound. The price received was 18.78c. The profit was $238,490, equal to $4 per share per annum, and $47,000 greater than in the preceding term.

At the Inspiration mine electric haulage underground has been displaced by compressed air locomotives. The Ray company at Ray is also reported to be about to use air.

GREENLEE COUNTY

On November 8 part of the militia was withdrawn from Clifton, as the strike situation continues quiet.

MOHAVE COUNTY

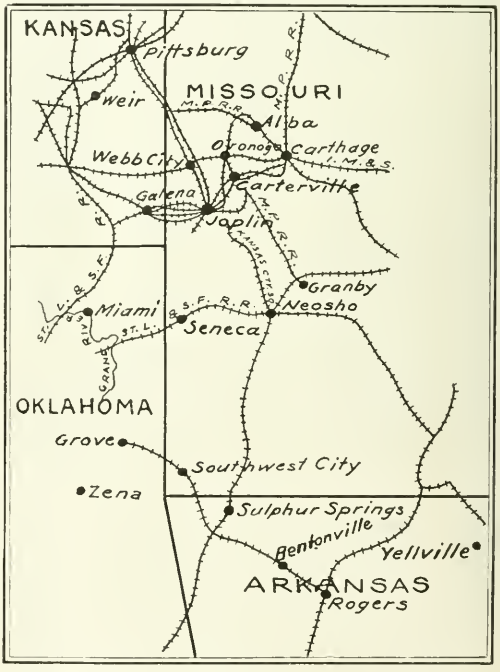
In the weekly news-letter of O. A. Turner of Kingman, a lot of interesting data is given on the mining centres of this county, producing mines, markets for ores, railroad rates and fares for ore and passengers, wages paid, and properties being developed. Oatman now has a population of 1300, an increase of 800 in four months.

At 280 ft. in the Golconda Extension zinc mine, shipping ore has been opened. The main shaft is being sunk to 500 ft. Dumps are estimated to contain $100,000 in zinc, gold, and silver. James Meikle is manager. The mine is in the Wallapai district.

ARKANSAS

MARION COUNTY

As the zinc regions of south-eastern Missouri, south-western Kansas, and north-eastern Oklahoma, are generally included under the heading of the Joplin district, it is suggested that the north-western zinc area of Arkansas be included, all being contiguous. The October production of the north Arkansas field was worth $120,000 for the zinc. Mines north and south of Yellville produced 1750 tons of blende. A number of mills are to be erected.



THE MISSOURI-KANSAS-OKLAHOMA-ARKANSAS ZINC REGION.

The Red Cloud mine at Rush is the largest zinc producer in Arkansas. The output in October was 250 tons of carbonate ore. E. Zimmerman is in charge.

Last week $100 per ton was paid for concentrate here.

CALIFORNIA

A good fall of snow is reported from most of the mountain counties, ensuring a good supply of water in the spring for hydraulicking, power, and other purposes.

Amador County

The Plymouth Consolidated company is sinking a shaft to 1200 ft. at the Montezuma mine, Nashville, Eldorado county. Three shifts of 20 men each are employed.

Four miles from Plymouth the Bay State mine is being reopened.

Butte County

At Oroville there are now only nine dredges at work, compared with four times that number several years ago. The Natomas Consolidated has three; Oro Light & Power, two; Oroville Dredging, two; Oroville Union, one, and Pacific, one.

Mono County

The Masonic district is looking brighter, due to renewed work at several properties, especially the Serita.

The Keane Wonder company's mine and mill, which were in financial difficulties, have been acquired by the Frances-Mohawk Mining & Leasing Co. of Goldfield, and others.

Nevada County

A change-house of 250-miner capacity is being erected by the North Star company at its Champion mine.

Shasta County

(Special Correspondence.)—The discovery of manganese ore in the Arps mine, near Copper City, has stimulated the search for manganese in the east side area of the Shasta copper belt. The deposit on the Arps has been traced for approximately 1200 ft., and is about 125 ft. wide. Samples of the ore assay 40% metal. Previous to the recent acquisition of the property by C. L. Wilson, of San Francisco, attention was paid solely to copper-bearing ore, and the presence of manganese was unsuspected. It is thought that this ore occurs on neighboring claims, and prospecting is active. The Arps is only a few miles from the Heroult smelter of the Noble Electric Steel Co. devoted to production of ferro-manganese and ferro-chrome. A shipment of manganese has been received at Heroult from the Woolley claims near Clipper Mills, Butte county, and is being tested.

The Mammoth Copper Co. has completed several improvements to its bag-house. Three blast-furnaces are in operation, and about 300 tons of Balaklala ore are treated daily, in addition to the ore from the Mammoth mines, and custom ores from several small copper and gold producers.

Operations have been resumed at the Menzel mine, on Flat creek, and 200 tons of ore on the old dump will be sent to the Mammoth smelter. Arrangements have been made for an electric power-line to the property, and unwatering of the shaft, which will be deepened. The mine was re-opened by Frank D. Earbert and M. A. Meagher.

The long drift from the 1300-ft. level of the Gladstone mine, at French Gulch, is expected to cut the orebody within two weeks. The vein yielded much rich ore in upper levels. Production has been curtailed pending further developments. Work is going on in the Five Pines, Summit, and other small mines in the French Gulch field.

Redding, November 15.

At Kennett the Mammoth Copper Co. is erecting a zinc-oxide plant to work in conjunction with its smelter bag-house. The company is laying a 4000-ft. air-pipe to the Friday-Lowden mine, after which the 4000-ft. adit will be started to open the Mammoth ore 500 ft. below No. 5 adit.

COLORADO

Clear Creek County

(Special Correspondence.)—Two feet of smelting ore has been cut in the winze being sunk on the Gunnell vein from the Argo adit-level, assaying $60 gold per ton.

G. K. Kimball and others, leasing at the East Lake mine, have opened 18 in. of ore that is settled at $35 gold per ton at the mill. Work is done through the Big Five adit.

August Swanson & Co., leasing on the Centennial vein of the Imperial Mining Co.'s estate, is shipping two carloads of ore per week, realizing an average settlement of $50 per ton in gold, silver, and lead. Stoping is in progress on a two-foot shoot.

The upper adit being driven on the Aetna vein of the Capital M. & T. Co.'s holdings, has cut 14 in. of lead ore, assaying 40 oz. silver, 0.50 gold, and 35% lead. Johnson & Kane are driving under contract, but hold leasing privileges.

Work was resumed last week on the Golden Glory adit on Saxon mountain. The opening has been advanced for 1720 ft., and a large cave near the breast is now being caught up, before extending the adit another 200 ft. J. F. Prichert is manager.

Large shipments are going out from the Linn mine on Democrat mountain. The 50-ton mill is working steadily and a good grade of concentrate is produced.

Idaho Springs, November 8.

In the East Argentine district J. C. Davis has found rich silver ore. During his prospecting he found some heavy rock thrown out from grading on the Argentine Central line, which on being analyzed proved to be high-grade wolfram. The deposit from which the mineral came is 14 in. wide. A rush has set in.

At the Capital mine the company and lessees are getting good returns. The mill is working, and shipping concentrate. ——The Malm mill is to be operated by the Colorado Metal Mining Co.——Lessees at the Waldorf and Onondago mines are also busy.

During October the W. J. Chamberlain Ore Purchasing Co. at Georgetown settled for over $14,000 of ore. There was 366 tons of ore marketed. The district is busier than for years.

Gilpin County

At a distance of over 665 ft. in its adit at Apex, the Pioneer Mining, Milling, Power & Tunnel Co., composed of Boston and New York people, a large lode has been opened, parts of it assaying high in gold, silver, and copper. The company has built a dam, power-plant, and stamp-mill, which will be started at once.

Concentrate from the Senator mine, below Black Hawk, have been settled for at 1.44 oz. gold, 23.75 oz. silver, and 11% lead, equal to $44 per ton; another lot realized $83.36 per ton.

Gunnison County

Mining has been quiet at the old centre of Vulcan, but a resurrection seems at hand, as the Good Hope, Vulcan, and Mammoth Chimney mines have been sold to Denver people. A 40-ton copper smelter is planned, also a hydro-electric plant.

Lake County (Leadville)

At the Penrose shaft of the Down Town property the pumps are working at 660 ft., lifting a large quantity of water.

An electric hoist is to be installed at the Matchless No. 6 shaft, costing $1350. Lessees have opened large bodies of high-grade iron ore in No. 5 and 6, from which the A. S. & R. Co. requires 1500 tons per month. In No. 7 32% carbonate of zinc ore is being mined.

Mineral County

(Special Correspondence.)—Lessees, employing about 10 men altogether, are working on the Bachelor, and are shipping about 150 tons per month.

Lessees at the Commodore are producing about 250 tons per month.

The Del Monte & Chance Mining Co., operating the Last Chance-Del Monte-New York, is shipping about 250 tons of ore per month.

The Mineral County Mining & Milling Co., operating the Creede United property and the Humphreys mill, is mining about 2500 tons of ore per month, from which is produced

about 350 tons of lead concentrate. It is also making a small amount of zinc concentrate, which is being stored at present. The ore is coming chiefly from the Happy Thought mine. The company is driving north on the Park Regent ground to prospect the Amethyst vein beyond the known orebodies. Two shifts are employed in the mine and one in the mill, about 65 men altogether.

The Syndicate Mining Co. of Kansas City, which owns some claims west of the Bachelor ground, is driving a cross-cut from the Nelson adit to prospect its property.

Schroder is doing some prospecting work on his claims south of the Bachelor.

Lessees are shipping a little ore from the Solomon.

It is reported that a combination of several of the companies owning ground on the Amethyst vein, to pump out the old Commodore shaft below the level of the Nelson adit, has been effected.

The fluorspar mine at Wagon Wheel Gap is being prepared to resume production. A tramway to bring the rock from the upper adit to the valley has been built, and shipping will be resumed shortly. The fluorspar is used as flux in the steel works of the Colorado Fuel & Iron Co. at Pueblo.

It is reported that some Del Norte people who are prospecting on Bear creek, 30 miles up the Rio Grande from Creede, have opened a vein of rich sylvanite ore, and will soon commence shipping.

Creede, November 6.

San Juan County

Ore shipments from Silverton in October totaled 134 cars.

At the Anti-Periodic property on Galena monntain near Silverton, the Rein adit is in 450 ft., and the vein is expected at any time, as the country-rock is mineralized and water increases.——The Garryowen adit is also in promising ground.——Development at the Buffalo Boy is encouraging.——The All O. K. adit is expected to cut ore soon.

The United States Mining Co. is to resume work in the Silverton district, in charge of E. C. Condit.——Eastern people are investing in the American Mining & Power Co.'s property near the Sunnyside mine.

Summit County

The Breckenridge district grows busier through its activities in gold dredging, lead-silver and zinc ores, and molybdenite mining. Flotation has been installed in the Montezuma and Philadelphia mills.

Teller County (Cripple Creek)

Three carloads of ore from a new shoot on No. 15 level of the Gold Sovereign mine on Bull hill were settled at 2.07, 2.24, and 2.17 oz. gold per ton respectively. The Union Leasing Co. has this ground.

The southern slope of Tenderfoot hill is very active on account of prospectors and lessees' work. Four properties are shipping ore; early in the year there was only one.

IDAHO

The extensive gravel areas in the northern part of this State and western Montana, which were worked years ago in a primitive manner, are receiving attention from Spokane people, who will commence work in the spring. L. F. Connolly, and his brother J. Connolly, of Spokane, are preparing to mine 400 acres on Tyson creek, a tributary of St. Maries river. Test by hydraulicking has been done this season, and by next June a plant costing $20,000 is to be erected. $30,000 net per acre is expected. Along the Yaak river Lincoln county, Montana, the Kootenai Hydraulic Mining & Power Co., of Spokane, will develop and sluice on its 1600 acres next year. Flumes, pipes, and hydraulic plant will cost $50,000. The gravel contains from 10c. per yard up.

The Orofino coalfield in Clearwater, Lewis, and Idaho counties is the subject of Bulletin 621-I of the U. S. Geological Survey, by Charles T. Lupton. He concludes as follows: The inferior quality of the coal and the fact that extensive prospecting in this region has failed to reveal coal in commercial quantities, suggest that the field will be of no importance as a producer of coal or lignite except in a very local way. It is questionable if any additional information regarding the coal or lignite possibilities of the general region, of sufficient promise to justify further prospecting, will be found, and the expenditure of time and money in such work is not advised.

Lemhi County

(Special Correspondence.)—At the Queen mine, north of Salmon, where work was resumed recently, 20 men are now employed in the mine and at the mill.——The Shoo Fly mines, which are situated on the divide between Wallace and Moose creeks, will be worked during the present winter under the management of J. B. Hastings. A shaft will be sunk, and other development done.——The dredge on Kirtley creek is working full time, and will continue so through the winter.

Leesburg, November 10.

Shoshone County (Coeur d'Alene)

Forty claims in the Beaver Creek district, nine miles northeast of Wallace, near the Interstate-Callahan, Ray Jefferson, Rex, and others, are to be developed by the Red Monarch Consolidated Mining Co., incorporated by Conrad Wolfle of Spokane, with a capital of $2,000,000 in $1 shares. Two adits are being driven, one to be 1000 and the other 4000 ft. long, while 8000 ft. of diamond-drilling is to be done. A 14-drill compressor has been ordered. Bunk and boarding-houses are being erected. R. H. Hewer is superintendent.

The National Copper Co.'s 500-ton mill resumed work on November 11. About 10,000 tons of ore is broken in stopes and in storage-bins.

Under the management of A. A. Dunphy, the Coeur d'Alene Antimony Co.'s Old Antimony mine, at the mouth of Pine creek, is the scene of considerable work. A mill is under construction, the process embodying jigs, tables, and flotation. The product will contain 50% antimony. One shipment of hand-jigged material assayed 38% metal, returning $1500 net.

MICHIGAN

The Copper Country

Men are plentiful in the district, none of the companies sending outside for help, but there are no unemployed. The miners, trammers, and mill men were never more efficient.

Rail connection has been made to the White Pine mine, and a large reduction in costs will result, especially in the carriage of fuel and mineral.

No. 3 test of the New Arcadian ore is underway at the Franklin mill.

MISSOURI

Jasper County

A 150-ton mill, driven by gas-engines, is to be erected in 50 days by the United Iron Works Co. for the Grand Tower Mining Co. Ore occurs in hard ground between 66 and 96 feet.

A 300-ton electrically-driven mill is being constructed for the Ben Franklin Mining Co. by the Webb City-Carterville Foundry Co. Operation is expected to commence in 60 days.

The sixth annual drilling contest of the Hercules Powder Co. was held at Joplin on November 7. A large crowd attended. The first prize of $100 and gold trophy hammer was won by B. Anderson, of the Steers & Rice mine, and I. L. Seagraves of the Geneva mine, Webb City, who drilled 37$\frac{11}{16}$ in. in 15 minutes. This beat the winners of 1914 by $\frac{3}{16}$ in. Second prize, $50, went to F. McCoy and J. Gates of the Lockport mine, Galena, Kansas, making a 36$\frac{13}{16}$-in. hole. H. Haines and O. Lewis of the C. & S. mine, Webb City, were third with 29$\frac{7}{8}$ inches.

MONTANA

The total assessed valuation of this State is $439,785,819; to which the mining county of Silverbow contributes $42,419,-

268, followed by Cascade with $31,649,303; Lewis and Clark, $24,151,849, and Fergus, $20,910,585. Railroad valuation is nearly $80,000,000.

Silverbow County

In the suit of minority shareholders in the Alice Gold & Silver Co. *v.* the Anaconda company, the Court some time ago ordered a re-sale of the former's property to see if higher than $1,904,390 could be secured, the price that the Anaconda paid. On November 10 there were no bidders, so the property passes to the Anaconda.

The Butte & Columbia Copper Mining company has commenced driving a 5000-ft. tunnel which will connect the Butte side of the Rockies with the Jefferson county side. At 3000 ft. the depth will be 1500 feet.

NEVADA

Humboldt County

(Special Correspondence.)—The Buffalo Valley Gold Mining & Leasing Co. has been superceded by a new company (name not yet decided). J. A. McAllep, of Valmy, Nevada, will be superintendent, and John T. Reid, of Lovelock, manager. Building will be started at once of a 100-ton mill (gold), with entire new mining and milling equipment. Water will be piped to the mill. This property has been under development for three years.

Valmy, November 18.

The new mill of the Nevada Packard company is practically complete. About 7000 tons of ore is ready in the mine.

At a depth of 425 ft. in the Rochester Mines ground the east vein is 21 ft. wide. It has been opened on the 150, 220, and 300-ft. levels.

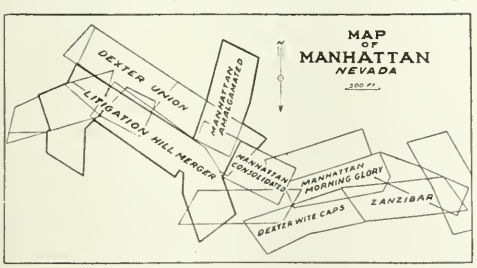
Rich ore continues to be extracted between 1200 and 1300 ft. in the Seven Troughs Coalition, and a four day's run of the mill last week yielded $8300. Exploration has been started at 1500 feet.

Mineral County

It is reported that bismuth ore has been discovered by W. R. Smith in the Cedar range, near the Copper Contact mine, and near Mina.

Nye County

The merger of the main mining properties on Litigation hill has been consummated, to be known as the Union Amalgamated Mining Co. Included in the merger is the Manhattan Milling & Ore Co.'s 10-stamp mill, cyanide-plant, and sampler. While the action of the directors of the various companies has to be ratified by the shareholders of the companies, there will be no difficulty in the obtaining of sufficient shares to vote in favor of the merger. All the large stockholders of the companies interested have already expressed themselves. The merger takes in the Manhattan Amalgamated Mining Co., comprising parts of three claims, the area of the claims being 23 acres free from conflict; the Litigation Hill Merger Mining Co., of parts of four claims, area 37 acres, and the Manhattan Earl Mining Co., area 14 acres. Three hoisting-plants, with orebins, transformers, surface track, ore-cars, etc., are already installed, and the electric mine pumps are at work draining the lower levels of the mine workings of each of the three properties. The main mining will be prosecuted through the Earl shaft, as it is 350 ft. deep, and connects with five levels. A summary of the ore produced by company and lessees shows the Earl to have produced 3948 tons, value $62,689, an average of $15.89 per ton; Litigation Hill Merger has produced 3918 tons, gross value $85,428, an average of $21.80 per ton; Manhattan Amalgamated has produced 1749 tons, gross value $35,731, an average of $20.43 per ton. An important orebody is already developed between the Earl and Amalgamated properties and from the 300-ft. level of the Earl proves to be from 4 to 8 ft. wide assaying $22.50 per ton. This orebody would have been the source of considerable apex litigation, if the present merger had not been consummated. A large quantity of medium-grade ore has been developed in the three properties by past lessees of the companies. This ore will average from $7 to $10 per ton, and although the lessees have been unable to mine and mill this grade ore at a profit; under company management, owning and operating its own mill, it will mean good profits over and above mine and mill costs.



THE CONSOLIDATED PROPERTIES ARE WITHIN THE DARK LINE.

At a directors' meeting of the White Caps Mining Co. held in Tonopah on October 27, definite action was taken toward the acquiring of the 10-stamp mill and cyanide-plant owned by the Associated Milling Co. The mill and all other assets of the milling company were purchased for 495,000 shares of White Caps treasury stock.

Last week the output of Tonopah mines was 9189 tons worth $191,362; lessees contributed 370 tons.

The Tonopah Mining property was inspected by directors, who are pleased with conditions generally. The mill treated 3100 tons of $12 ore last week.

At 1350 ft. in the Extension the ore-shoot has been opened for 450 ft., with no sign of the end, with great width and high value.

OKLAHOMA

Fifteen new concentrating plants will soon be increasing the output in the north Oklahoma zinc region if information recently gathered by the Miami *Record-Herald* is correct. A list of these plants with their nominal tonnage capacity follows:

Mills.	Tons.	Mills.	Tons.
Beaver	200	Picher	300
Blue Goose	200	Picher	300
Century	150	Picher	300
Croesus	200	Picher	500
Hannibal & St. Joe	150	Red Feather	200
Katy	250	Welch	200
Mission	400	White Eagle	200
Myrtle	200		
		Total	3750

This practically assumes a one-third increase in the production of concentrates in the Oklahoma field, as the present capacity per shift is reported at 6250, listed as follows:

Companies.	Tons.	Companies.	Tons.
Carson Mining Co.	400	Lost Trail M. Co.	250
Carson Mining Co.	200	McConnell-Barnes	200
Concentrating Co.	150	McConnell Zinc Mines	450
Cornfield L. & Z. Co.	250	Midas L. & Z. Co.	150
Cactus Mining Co.	250	Miami L. & Z. Co.	400
Denver-Miami M. Co.	200	Miami Amalgamated	250
Emma Gordon	400	Mizpah M. Co.	250
Eureka Mining Co.	150	Never Sweat M. Co.	200
First Chance M. Co.	100	Old Chief	150
Golden Hen M. Co.	150	Prairie M. Co.	250
High Five M. Co. (tailing mill)	200	Quapaw M. Co.	250
Kansas Mining Co.	50	Queen City-Joplin	200
Kansas Tailing	50	Turkey Fat M. Co.	250
Lennan L. & Z. Co.	300	Vantage M. Co.	150
		Total	6250

OREGON

The U. S. Geological Survey has just published its mines report on gold, silver, copper, lead, and zinc in Oregon in 1914, by Charles G. Yale, who states that there was a material decrease in the number of producing mines, namely 68. Everything showed a decrease, as follows, the figures for 1913 being in parentheses: mines producing, 105 (173); ore extracted, 124,331 tons (155,901); gold, $1,591,461 ($1,627,710); silver, 142,552 oz. (179,036); copper, 39,248 lb. (43,330); lead, 16,436 lb. (87,207); and total value, $1,676,153 ($1,746,402). Deep mines yielded 50,388 oz. gold, and placers 26,525 oz. Hydraulic,

MAP OF OREGON.

drift, and surface and dredge work produced $178,899, $4426, and $364,992 respectively. Amalgamation at quartz mines recovered $333,768 and cyanidation, $594,861. Baker county produced most of the gold from mines and placers.

Baker County

The Mother Lode properties in the Cracker district have been examined by J. A. King of the Tonopah Belmont company, Nevada. If satisfactory, the report will result in a consolidation of the North Pole, Eureka, Excelsior, Taber fraction, Columbia, and Golconda. It will be the largest deal ever consummated in Oregon. The North Pole mill is working satisfactorily.

SOUTH DAKOTA

Lawrence County

Prospecting in the Two Bit district is being actively carried on with little publicity, and results are encouraging.

Pennington County

Renewed activity is reported from the old Tigerville district, near the Burlington railroad's Redfern station. The King Solomon shaft will be unwatered and the mine examined. Other properties nearby are the Slogan and Bullion.

TEXAS

Brewster County

(Special Correspondence.)—Development of quicksilver properties in the Terlingua district is stimulated by high prices for the metal. The Chisos Mining Co. is the principal operator and producer. The Study Butte company is extracting high-grade ore. The claims of W. P. Gaines and others of Austin contain deposits of cinnabar, and a sale to Philadelphia people is likely.

Terlingua, November 5.

Live Oak County

(Special Correspondence.)—Following a preliminary examination of the potash deposits in this district, the U. S. Geological Survey has sent in equipment to explore the material underground, in charge of S. H. Walker. The State University is also to survey the so-called bad lake region of Lynn county, where potash is thought to occur.

Simmons, November 5.

UTAH

Boxelder County

The Lakeview Mining Co. at Promontory Point has declared its fifth dividend, of 2½c. per share, equal to $11,250. Another company is to commence work in this area.

Juab County

On November 26 the May Day company will pay 3c. per share, equal to $24,000. Lessees are also doing well.

Salt Lake County

At Lark the Ohio Copper Co. is to erect a 25-ton Field's flotation-plant, similar to that installed at the Royal Basin mine, Maxville, Montana. There is a large quantity of tailing also worth treating at Lark.

Summit County

The Snake Creek tunnel was advanced 312 ft. in October, the face now being in 13,025 ft. The flow of water is larger.

The strike at the Silver King Coalition mine has been called off.

It is reported that an adit 14,000 ft. long may be driven to develop the western ground of the Silver King Consolidated. A site for the portal and mill will probably be on Three Kings ground.

WASHINGTON

Ferry County

The Knob Hill Mining Co., which owns and is operating the Knob Hill and Mud Lake mines at Republic, has purchased the Alpine claim, adjoining the Knob Hill on the east, at a reported price of $20,000, according to information received in Spokane. The initial payment of $5000 was made on October 25, and the remainder is to be paid in $5000 installments at 12 months' intervals, with deferred interest at 5%. The Alpine claim was owned by Jonathan Bourne of Portland, from whom the Knob Hill company acquired the Knob Hill and the Mud Lake. "Engineers who were employed by the Knob Hill company to examine the Alpine ground, state that acquisition of the property enhances the value of the consolidated holdings not less than 35%," states John G. LaRue, who made the announcement of the deal.

Spokane County

The Spokane Stock Exchange has decided to establish a mines publicity bureau, to distribute news concerning mines in the region contiguous to Spokane.

Stevens County

At the Northport smelter there are 240 men employed in reconstruction. Foundations, three-mile flume, reservoirs, and other work are making good progress. The Electric Point mine, 26 miles away, is producing rich lead-silver ore, and will send it to the new smelter when complete.

WISCONSIN

LaFayette County

(Special Correspondence.)—At Benton the Frontier Mining Co. is building a new surface plant on the Treganza.——Another new plant is proposed for the Hird mine. This company has paid $200,000 in dividends during the past six years.——The Longhenry Mining Co. is installing new equipment.——Misabi type pumps have been installed at the Kittoe mine: 1700 gal. is lifted 200 ft. per minute.——Two new separator-plants are working successfully.——Four miles of macadam road is being built to connect all outlying producers.

The United States Steel Corporation is operating in the Shullsburg district, and is rushing a new mine plant to completion.——The Winskill mine is producing heavily.

At New Diggings the Vinegar Hill Zinc Co. is building a

new power-plant and mill on the Blackstone lease recently drilled. The Wisconsin Zinc Co. will start a new $75,000 electro-static separating-plant on the 20th.——The Champion mine is producing 400 tons of ore per week.——W. W. Seaver of Pocatello has acquired the Booty lease, and will drill it at once.——The Crawhall mine, once a famous dividend-payer, is worked out and will be abandoned.

Benton, November 10.

WYOMING

Bighorn County

The great gas-well at Byron has been capped. There is great excitement and much activity in Elk basin, near the Montana and Wyoming line, as oil has been discovered recently. Drilling rigs are being rushed in, and people are flocking for locations. Two or three wells have been brought in already and the field promises to be an exceptionally good one.

CANADA

British Columbia

It is stated that all mines in this province are producing about 11,000 tons of ore daily, over 4000 tons coming from the Boundary district, and over 3000 from the coast. The completion of works now under way is expected to make possible an increase in the daily tonnage of the province to 20,000.

The Jewel-Denero property near Greenwood has been leased.

A new $60,000 bridge was completed last week for the Great Northern line over the North Fork canyon to the Granby smelter at Grand Forks. A year ago the Canadian Pacific also erected a bridge, costing $100,000.

Ontario

In part of the town of Cobalt the Coniagas company has three drills under the Hunter block and under Argentite street on exploration, and six stoping and on development. The new canvas-plant is treating up to 80 tons of slime per day from the concentrating-plant, making a 130 to 150-oz. product. A cyanide-plant to treat this material will soon be ready. About 120 men are employed.

The deepest shaft at Cobalt is at the Beaver mine, it being 1228 ft., with sinking still in progress until the diabase is reached. Development is under way at 300, 400, 460, 530, and 600 ft. There are 130 men employed. While silver is low no attempt is made to produce much ore.

During October the Nipissing high and low-grade mills treated 87 and 7272 tons of ore respectively, yielding $177,183. The refinery shipped 486,901 oz. silver, some being from custom work. The Cobalt Lake fault-vein is to be explored in Nipissing ground. Prospecting by hydraulicking continues.

The Canadian Copper Co. has taken an option on a copper claim owned by Smith and Durkee of Sudbury, located in Connaught township, east of the West Shining Tree gold area.

The demand for molybdenite for steel hardening in England has encouraged its production in Canada. The Orillia Molybdenum Co. of Orillia, Ontario, is now treating molybdenum ore, and last week made its first shipment of concentrate to the British war office. Consignments will be forwarded weekly.

MEXICO

Hidalgo

From the treatment of 16,535 tons of ore in September the Santa Gertrudis profit was $39,000.

Sonora

Owing to the Villa activity in this State, exports of minerals to Arizona decreased during October. The total was 134 cars, containing 4689 tons, of which 4160 tons was from the Moctezuma at Nacozari and 131 tons from El Tigre, the latter shipping 55 bars of bullion. The value of exports was copper ₱722,000; silver, ₱293,000; and gold, ₱186,000, a total of ₱1,201,000.

PERSONAL

H. H. Webb has gone to New York.

Arthur Winslow is here from Boston.

Ben. S. Revett has returned to Denver.

S. A. Worcester is at Ouray, Colorado.

L. D. Ricketts was here during the week.

J. W. Malcolmson is at Douglas, Arizona.

J. H. Mackenzie has returned from Juneau.

R. Gilman Brown has returned to London from Siberia.

Walter G. Perkins is on a visit to New York, from London.

R. T. Mishler, metallurgist to the El Tigre, Mexico, is here.

Thos. B. Stearns, of Denver, has been visiting the Exposition.

J. Power Hutchins has returned from the Altai to Petrograd.

Leo Von Rosenberg was in the Ray district, Arizona, last week.

Jack Reid, of Good Springs, Nevada, has been visiting the Exposition.

Charles A. Banks has gone from Greenwood, B. C., to Edinburgh, Scotland.

A. D. Hughes has returned to San Francisco for the winter, from Atlin, B. C.

Robert H. Bedford has returned to Grass Valley from a visit to Douglas, Arizona.

G. A. Joslin has been appointed engineer with the Ray Consolidated, in Arizona.

J. Parke Channing was here this week and is now on his way back to New York.

Jesse J. MacDonald is the representative of the Pacific Mines Corporation at the United Verde Copper Co.'s smelter, at Clarkdale, Arizona.

George B. Holderer, who recently returned from South America, has been appointed general manager for the Furlough Development Co., which is developing a copper property near Wickenburg, Arizona.

Alberto E. Blair, manager for the Madero estates in Mexico, was ordered to leave Torreon by the Carranza authorities on the ground that the Madero family, with the exception of Julio Madero, had supported Villa. He refused and appealed to the British embassy at Washington.

Schools and Societies

The second session of the Prospectors' Short Course at the Mackay School of Mines of the University of Nevada, will be held from January 30 to February 26, 1916. The work of the course will include both lectures and laboratory exercises, and the subjects taken up will be prospecting, assaying, mineralogy, geology, prime movers, chemistry, hygiene, sanitation, first aid to the injured, and mining law. In addition to these regular courses there will be a number of special lectures upon subjects of interest to the prospector.

The ordinary general meeting of the Chemical, Metallurgical and Mining Society of South Africa was held at Johannesburg on September 18. Papers were read as follows: 'An Improved Method of Removing Broken Ore from Stopes,' by M. Weinbren; discussion on notes previously read; 'Cyanide Consumption on the Witwatersraud,' by H. A. White; 'The Prevention of Hydrolysis in Cyanide Solutions,' by H. M. Leslie; reply to discussion: 'Safety Measures in the Use of Explosives,' by William Cullen; 'The Use of Scoop Discharges in Tube-Mills,' by W. R. Dowling; 'Notes on the Practical Testing of Working Cyanide Solutions,' by Edward H. Croghan; continued discussion: 'Notes on the Treatment of Antimonial Gold Ores from the Murchison (Transvaal) Range,' by H. R. Adam; 'Recent Investigations on Dust in Mine Air and the Causation of Miners' Phthisis,' by James Moir.

THE METAL MARKET

METAL PRICES.

San Francisco, November 18.

	Cents per pound.
Antimony	37
Electrolytic copper	19
Pig lead	5.50—5.70
Quicksilver (per flask)	$100
Spelter	17
Zinc-dust, 100-kg. zinc-lined cases	25

ORE PRICES

Antimony: 50 and 60% products, per unit.....$1.60 and $2
Magnesite: calcined, per ton $30
Manganese, 50% metal, 8% silica, per ton..... 12
Molybdenite: 90% MoS_2, per pound..... 1.50
Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....$35—40

New York quotes $41 per unit for 60% tungsten ore, prompt delivery, first half 1916, $38; for antimony ore, $2.25 per unit for prompt from South America; for manganese ore (Brazilian) 46 to 50c. per unit; and 96c. to $1 per pound for vanadium oxide, 80%.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 18.—A large business is being done in copper, resulting in a strong upward movement; lead is strong, with large export sales; the zinc market is excited, heavy inquiries are reported.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Nov. 11	50.25	Oct. 6	49.64
" 12	50.25	" 13	49.55
" 13	50.25	" 20	49.53

May	58.21	49.87	Nov.	49.12	....
June	56.43	49.03	Dec.	49.27	....

The above steady increase in price indicates a firm market with something behind it.

Exports of silver to India and China to October 27 total £3,400,250 against £4,721,500 in that period of 1914, a decrease of say 14,000,000 oz. Stocks in London are about 14,000,000 oz. Trouble in the Mediterranean Sea and Suez Canal may hold-up shipments to the Orient. Good reports have been received in London concerning the weather in India, a factor in the silver market, especially in the Gujurat district. The position of India in silver is considered remarkable at present, as stocks have increased in spite of few new imports of metal of late.

COPPER

Prices of electrolytic in New York, in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Date.	Week ending	Nov. 4	97.50

Tin is firm at 42.50 to 43.50 cents.

ANTIMONY

Chinese and Japanese are quoted at 36 to 36.50c., duty paid. Offering of December shipments from the Far East have been made at 32c. c.i.f., about equal to 35c.

ALUMINUM

Quotations for No. 1, 99% pure are nominal at 56 to 58c.

Eastern Metal Market

New York, November 12.

The activity referred to a week ago has continued; a good volume of business was done in the leading metals, and prices of all have mounted to higher levels. Millions of pounds of Lake and electrolytic copper have been sold, and the Lake producers are in a particularly good position. Zinc has advanced steadily, and carried with it the price of sheet-zinc. Lead was advanced $5 per ton within the week, and consumers bought on the rise. Tin advanced sharply because of a shortage in the supply, and fear that deliveries may be halted by the submarine warfare in the Mediterranean. Antimony is quiet, but firm at its high level. The nominal price of high-grade aluminum is 56 to 58c. per pound.

Big deals to merge iron and steel companies, and even to secure control of machine-tool plants, continues to absorb much attention from investors. How busy the steel industry is at present is indicated by the fact that the United States Steel Corporation's unfilled orders increased 847,000 tons during October. The increase breaks all records. The prices of finished and semi-finished steel are advancing on every side; in fact, the question today is more one of getting deliveries than what price shall be paid. The value of iron and steel exports, including machinery, was $38,400,000 in September, against $37,727,000 in August. Large shipments of railway equipment and other machinery are in transit to Vladivostock, to say nothing of enormous quantities sent to Europe. The Pittsburg base for plates, shapes, and bars is 1.60c., but premiums of $1 and $2 per ton are easily obtainable.

COPPER

Up to the end of last week a heavy business was done for export, while domestic consumers having war contracts took good-sized quantities as well. Most of the buying was at 18c., New York, or near that figure, and both electrolytic and Lake were taken, with the latter getting what ordinarily would be considered more than its share. One Lake producer sold in one month more than he can produce in four months. As one result of the recent activity, Lake promises to again be held at a premium, though not a large one. At the end of the week electrolytic was advanced to 18.12½c. cash, New York, and Lake to 18.25c., cash. Second-hands did not cut much of a figure in the movement, either because they did not have the metal, or were holding for higher prices. This week the market has been strong, but there has not been much doing. The copper sold for export was taken by England, France, and Sweden, the latter country taking several hundred tons. The action of the producers in booking orders for probably 60,000,000 lb. without letting the market run away with a too rapid advance in prices, which would at least have temporarily put a quietus on activity, is commended by the trade generally, as all interests fare better on such sane procedure. Choice Lake copper is quoted at 18.37½ to 18.50c., cash, and one producer is sold up to next June. Mention of high-grade copper recalls a story that is going the rounds of a fuse and shell contractor, who some months ago gave an order for 1,000,000 lb. of 'copper.' When delivery was made, the mill that was to work up the metal, refused to accept it because of its inferior grade. Through the medium of a broker the entire shipment was thrown on the market, and sold to several consumers. But the end is not yet, for the producer only agreed, at the price involved, to deliver the metal to one point in the Naugatuck valley. The original buyer has war contracts running into many millions. The London market for electrolytic has been extremely strong, and on November 11 was quoted at £91, compared with £88 not many days ago. Spot standard on that day was quoted at £75 10s., making a difference of about £16. Exports from 1st to 12th totaled 4588 tons.

ZINC

Steadily increasing strength has marked this metal and with the advancing prices a large business has been done between 15 and 16c., New York, for prompt and nearby. Both foreign and domestic buyers have taken zinc, the latter buying extensively into the first quarter of 1916 at prices ranging from 14.75 to 15c., New York. The St. Louis quotation for first half delivery is from 13.50c., St. Louis, or 13.75c., New York, to 14c. With the quotation for prompt at 16c., it looks as though sellers are trying to stimulate the buying of futures. Horsehead spelter has been sold well into next year at 40c. Extra refined prime Western spelter has been freely offered as a substitute for the naturally choice grades at from 25 to 28c. per lb., but not all of the consuming trade take kindly to it, which may be due to the prejudice which invariably plays its part where consumers get used to certain grades or brands. What with the steadily advancing prices for steel, and the higher price of spelter, makers of galvanized sheets will be confronted with the necessity of making further advances in the quotations for their product. They now quote No. 28 galvanized sheets at 3.80 to 3.90c. The exports of spelter continue at an excellent rate, those of the month up to November 12 totaling 1163 tons. From abroad it is reported that shipments from this country have been delayed, and that some September contracts are still unfilled. Spelter advanced £8 per ton in London, November 11, making the quotation £85 10s., equal to over 16c., New York, discounting freight and insurance. The base price of sheet-zinc, carload lots, f.o.b. mill, was advanced on November 4 to 16.50c., and again on the 9th to 17c.

LEAD

The A. S. & R. Co. advanced its New York quotation $2 per ton, or to 5c. per lb., on November 4, and on the 10th announced a further advance of $3 per ton, making the price 5.15c. per lb., New York. St. Louis quotations were 10 points below these prices. The first advance, like the previous one to 4.90c., New York, surprised the trade, but had the effect of stimulating buyers, and created activity on both foreign and domestic account. Before the upward trend was inaugurated, the market looked weak, and independents were cutting prices to get business. They continued this policy to a less extent after 5c. was reached, and ceased when the market went to 5.15c. All interests are well sold up. Two theories are put forth to account for the advance, one being that the leading interest has booked large export orders, and the other that the seizure by Villa of certain plants in Mexico may curtail the English supply. London is firm and advancing.

TIN

For some time there has been developing a scarcity in spot tin, and under this influence prices have advanced, the quotation on November 10 reaching 37c. The activity of submarines in the Mediterranean and the loss of several vessels there has caused uneasiness, also unconfirmed news that the Suez Canal was to be closed for military reasons on November 11 sent the spot quotation up to 43c. In warehouses there are considerable quantities of tin, but apparently these are owned by consumers. Banca tin is now selling in this market at from ⅛ to ¼c. under Straits. Makers of tin-plate have been fairly good purchasers of futures in the past few days, but on the whole the market has been quiet, and business has been done by a few hands only. Good round lots of spot are almost impossible to obtain. The arrivals up to November 12 totaled 975 tons, and there was afloat on that day 4703 tons, not all of which will arrive this month. Arrivals at Pacific ports in September were 71,847 lb. at San Francisco, valued at $21,624, and 939,942 lb. at Seattle, valued at $324,354.

COMPANY REPORTS

GRANBY CONSOLIDATED MINING, SMELTING & POWER CO.

For the third quarter of 1915 the Granby Consolidated reports as follows:

Ore treated, tons	521,252
Copper, pounds	12,057,385
Gold, ounces	14,849
Silver, ounces	177,610
Cost at Anyox and Grand Forks, cents per lb.	7.939 and 10.91
Gross income (including 8,385,100 lb. at 15.5c. unsold)	$2,310,262
Profit	486,436
Dividends	224,978
Surplus (bond interest deducted)	206,210

CHINO COPPER CO.

The third quarter of this New Mexican property resulted as follows:

Overburden removed, cubic yards	841,055
Ore treated, tons	690,400
Average copper-content, per cent	1.98
Extraction, per cent	67.82
Metal output, pounds	18,545,638
Cost, cents per pound	7.18
Profit	$1,555,414
Dividends	652,455
Surplus	902,959

An average of 16.003c. per lb. was received for copper, against 17.54c. in the previous quarter, resulting in less profit. Costs were higher due to a lower grade ore. Recovery was higher.

NEVADA CONSOLIDATED COPPER CO.

The report of this company for the September quarter has the following:

Overburden moved, cubic yards	866,713
Ore treated, tons	837,374
Average copper-content, per cent	1.66
Metal output, pounds	18,516,121
Cost, cents per pound	8.01
Profit	$1,590,621
Dividend	749,796
Surplus after depreciation and ore extinguishment	612,352
Total surplus ($243,937 cash)	3,335,040

Profits were $226,528 greater than in the preceding quarter.

The average price of metal was 15.876c. per lb. Of the ore treated 98% was from steam-shovel work. The Ruth mine is ready for active production of ore.

UTAH COPPER CO.

The Utah Copper Co. reports as follows for the third quarter of 1915:

Capping removed, cubic yards	1,617,779
Ore treated, tons	2,498,400
Average copper content, per cent	1.4089
Extraction, per cent	63.59
Metal output, pounds	44,766,841
Net cost, cents per pound	7.64
Net profit from mine	$3,663,708
Net profit from all sources	4,414,564
Dividends	1,624,490
Surplus	2,790,074

The amount of overburden removed was an increase, and the quantity treated was 283,241 tons greater; the output was about 4,000,000 lb. more, but profits were almost the same. Business on the Bingham & Garfield railroad was good.

RAY CONSOLIDATED COPPER CO.

The third quarter of this Arizona company showed as follows:

Underground development, feet	12,205
Ore mined and treated, tons	716,211
Cost of mining and coarse crushing, cents per ton	70.835
Average copper content, per cent	1.659
Cost of treatment, cents per ton	56.54
Metal from mill and crude ore smelted, pounds	15,382,354
Price received, cents per pound	15.709
Cost, cents per pound	10.199
Net profit	$781,272
Dividends	547,801
Surplus	$233,471

The profit was $564,961 less than in the previous quarter, while the output was somewhat higher; but a lower price for copper, alterations to plant, and labor troubles all helped to lower the profit.

CONSOLIDATED INTERSTATE-CALLAHAN MINES CO.

The report for the third quarter of this great Idaho zinc mine contains the following:

Ore treated, tons	29,021
Crude ore shipped (40.68% lead, 19.54 oz. silver) tons	203
Crude ore shipped (49.01% zinc) tons	2,506
Concentrate shipped (53.33% lead, 23.86 oz. silver) tons	792
Concentrate shipped (48.06% zinc) tons	11,942
Extraction of zinc, per cent	84
Cost of mining, per ton	$3.389
Cost of treatment, per ton	$1.082
Cost of shipping, per ton	$1.190
Total	$5.661
Net profit	$863,192
Dividends, two of $2.50 per share	$1,162,375
Surplus	$795,679

All additions and improvements to the mill are finished. The aerial tram is saving $5500 per month. Cottages were built, also a rooming-house for 200 men, while a boarding-house is under construction.

TOMBOY GOLD MINES CO., LTD.

The report of this Colorado property covers the year ended June 30, 1915, and that of D. A. Herron, general manager, contains the following information:

Work in the Argentine mine totaled 427 ft., of which 133 ft. was between the 1900 and 2100-ft. levels, the remainder at 2200 ft. The drifts were extended as far as ore was considered profitable, and contained $2 to $3 in gold and silver, and 2 to 4% lead. All stopes above 500 ft. have been drawn, and all available pillars supporting that level removed. Ore reserves in the Argentine are 185,000 tons, of which 135,000 tons is broken in stopes. In the Montana mine development covered 5936 ft. After considerable trouble ventilation was improved. The 1150-ft. level was extended nearly 2000 ft. The Fortuna, 1450 ft., 1600 ft., and Ophir levels made good progress northward, also at 1900 ft. While not as good as last year, results are encouraging. Reserves are 350,000 tons, 200,000 tons being broken in stopes. A snow-slide held up the aerial tram for 96 hours.

The 60-stamp mill and concentrator operated satisfactorily, but improvements had to be made to the cyanide-plant. The revenue from mill bullion, cyanide bullion, and concentrates from 145,857 tons of ore, was $7.05 per ton, at a cost of $4.49 per ton.

Total revenue was $1,050,870, of which $396,223 was profit. With the balance of $230,000, there was available $626,223, of

which $226,000 was paid in dividends. After allowing for depreciation, income-tax, etc., the balance was $110,000.

BROKEN HILL PROPRIETARY CO., LTD.

The report of this well known Australian company for the half-year ended May 31, 1915, is interesting on account of the variety of contents, namely, mine operations, concentration, smelting, and the new steel plant, the last mentioned being recently commenced at a cost of about $6,240,000.

The mine produced 109,911 tons of ore. The crude-ore mill treated 90,248 tons of crude ore and 11,449 tons of dump-tailing; and the re-grinding plant 82,140 tons of dump-tailing and 1712 tons of jig-tailing, producing a total of 17,900 tons of lead-silver concentrate. The flotation-plant treated 139,763 tons, yielding 33,318 tons of concentrate assaying 46.95% zinc, 12.48% lead, and 6.26 oz. silver. The sulphuric acid plant produced 1826 tons of strong acid.

The Ropp roasting-furnaces and Dwight-Lloyd plant treated 42,752 and 52,408 tons of concentrate, etc., respectively. The smelter at Port Pirie reduced 124,424 tons of mixed material, yielding 59,742 tons lead bullion. The lead refinery produced 46,168 tons lead, 362 tons antimonial-lead, and 1,912,205 oz. silver. The spelter plant yielded 2471 tons spelter and 381 tons blue powder.

Revenue from metals, custom smelting, iron and steel sales, etc., totaled £881,150, of which £272,279 was gross profit. Depreciation, various offices and agencies, funds, taxes, etc., totaled £93,438. Two dividends, No. 169 and 170, absorbed £118,100. The surplus is £1,062,809, including £165,624 cash.

Good orders have been received for iron and steel products, work being assured for a year ahead. The report is replete with plans, photographs, and other information.

JUMBO EXTENSION MINING CO.

The report of the Jumbo Extension Mining Co., Goldfield, Nevada, for the third quarter of 1915, shows a production of 8577 wet tons of ore, having an average assay-value of $39.53 per ton, according to mine sample. This ore was mined at a cost of $23,340 or $2.72 per ton. All this ore was produced from the Velvet claim and shipped to the Western Ore Purchasing Co. A total of 1782 ft. of development work was performed from No. 1 shaft, at a cost of $12,416, or $6.97 per ft. No. 2 shaft was lowered 301 ft., at a cost of $9826, or $32.65 per ft. The total cost of mining, development, and repairs, which includes overhead and administrative charges, is $4.37 per ton of ore produced.

Following is a summary of receipts and disbursements for the period ended September 30:

Revenue.		
Smelting ore sold		$325,041
Freight and treatment	$73,275	
Sampling	5,406	
Smelting losses	37,721	116,402
Net returns from ore sold		$208,639
Costs.		
Mining	$23,340	
Development	12,416	
Repairs	1,766	
Velvet shaft	9,826	47,348
Net realization from operation		$161,291

A plan is now being considered by the company to form a subsidiary company on the Diamondfield portion of its property to work the ground on an independent basis. It is not contemplated to use any funds derived from operations on the Poloverda or Velvet claims, but to place the junior company on its own merits. Final plans will be announced later. The new company will have the same management as the Jumbo Extension.

BOOK REVIEWS

How to Make Low-Pressure Transformers. Second Edition. By F. E. Austin, Hanover, New Hampshire. For sale by the Mining and Scientific Press. Price, 40 cents.

This little book is a companion to the author's work on the design, etc., of high-pressure transformers, and from it amateurs and others will be able to construct their own apparatus. Transformers appear to be complicated to the layman, and here is everything easily explained.

Design of Steel Bridges. By F. C. Kunz. P. 461. Index, and appendix with 52 plates. McGraw-Hill Book Co., Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $5.

The author states that this volume is to be the first of four on different branches of structural engineering. It is a practical text-book dealing with the design of the different types of steel bridges most commonly used. The first chapter considers the several forces acting upon a bridge truss, following which the determination of stresses in the different parts of a bridge is discussed. Then comes the design of the various parts of a simple truss bridge from the floor system up. The calculation of stresses and the design of viaducts, elevated railroads, and movable bridges are then taken up in order. Under arch bridges, the two-hinged and three-hinged, but not the hingeless, arches are considered. Cantilever bridges are then discussed, but suspension bridges are not considered in detail. The appendix contains data on the bearing pressure for foundations, specifications, and similar matter. There are a large number of tables and diagrams illustrating the text, and the plates give examples of accepted practice in the various branches of bridge design. While lack of attention to details is shown by such statements as that on page 215, that the length of spiral is always 720 times the super-elevation, and the one on page 368 placing the Columbia river in California, the book in general will prove of considerable value to the bridge engineer and the student.

The Elasticity and Resistance of the Materials of Engineering. By William H. Burr. P. 919. Ill., index. John Wiley & Sons, Inc., New York. For sale by the Mining and Scientific Press. Price, $5.50.

This is the seventh edition of this valuable treatise, which appeared first in 1883. Much new material has been added since the last edition and a large part of the book has been re-written. In particular, the section on reinforced concrete is almost entirely new, the design of columns and beams of this material being taken up in considerable detail. The first two chapters of the book are devoted to the general theory of elasticity and of flexure, including a discussion of shearing stresses. Torsion is then considered and the resistance of various materials when subjected to this form of stress is given. The next chapter considers the strength of hollow cylinders and spheres. Then come discussions of resilience and of combined stresses. The second part of the book takes up the properties of the various materials of engineering with reference to both tension and compression. Riveted joints and pin-connections are next considered. The treatment of long columns of various materials is thorough. Beams and plate-girders are next considered. Stressses in various miscellaneous articles such as hooks, springs, rollers, spikes, etc., are then discussed. Two chapters are devoted to the fatigue of metals and to the flow of solid bodies under stress. The principal appendix contains a theoretical discussion of elasticity.

NEW MACHINES AND DEVICES

Information based on letters and catalogues from manufacturers.

Air-Feed Hammer-Drill for Driving

By FREDERICK W. COPELAND

This machine may be summarized as follows:

A light, rotating hammer-drill, with water-jet attachment, mounted on a pneumatic-feed cylinder, with offset arm to be clamped in an ordinary trunnion, and mounted on a column arm or tripod. It is intended for driving, and in this work saves time and labor as the air-feed of the stoping hammer-drill does in drilling upper holes. The drill may be removed from its mounting, and used either as a stoper or as a hand-sinker, or block-hole drill. A close approach is thus made to the ideal, one-man, universal drilling machine.

The ambition of modern designers has been to develop a practical driving machine, operated by air-feed. As is well known, the elimination of the shell and feed-screw form of mounting in the modern stoping-drill, and the substitution of the air-feed cylinder and piston, resulted in a great increase in drilling speed in all upper hole work. Air-feed stopers, in spite of the fact that a striking plug or anvil is employed, secure high speed, because of the fact that the air-feed holds the bit constantly against the rock, so that any break in its character is followed instantaneously by the steady push of the air. In the case of the screw-feed, the operator must catch the sound of the hammer, (providing he is operating a hammer type of drill) as it strikes the front-head; and take up the slack with the crank before the drill can work again at full load.

Effort has been made by means of what is known as the 'reverse-feed' cylinder to adapt the stoping-drill to driving work. This has been only partly successful, being useful mainly as a temporary expedient in work of short duration or in development. One difficulty encountered was the fact that the rate of feed cannot be varied, as it can with the feed-screw machine; if the cutting is soft or uneven, a stoper will drive forward as the resistance decreases and bind the bit. This necessitates freeing the steel by hand, with loss of time and effort on the part of the runner. If the reverse-feed stoper is fitted with an extra light feed, to handle soft cutting in ore, no impression will be made when hard rock is encountered. Another objection is that the length of the stoper, when arranged for driving, makes it clumsy to operate in cramped quarters and difficult to dip for cut holes, as the long feed-cylinder strikes the roof.

The problem of eliminating the feed-screw and crank, with its attendant reduction in drilling speed, loss of time in moving, changing steel, etc., is claimed to have been solved, and the result embodied by the Sullivan Machinery Co. in a new type of mounting for its automatically-rotating, hand-feed hammer-drill. The idea for this mounting came from southeast Missouri, where a home-made appliance, for mounting hammer-drills for driving in disseminated lead ore formation, showed promise. The perfected mounting consists of a feed-cylinder and piston, similar to the reverse-feed type employed for mounting stopers. Instead of one port leading to the back end of the cylinder, to drive the feed piston, and with it, the drill, forward against the work, there are two ports in the piston-rod, one-conducting the air to the rear end of the feed-cylinder, and one to a point just forward of the feed-piston. By this means, an advantage is secured, namely, the drill is not only advanced to its work by air power, but is withdrawn from it by the same means. As desired, air can be admitted to the rear of the feed-cylinder only, to carry the drill forward against its work; to the front end of the cylinder only, to carry the drill and steel back from its work; or to both sides of the feed-piston at once, in which case a forward feed of modified strength is secured. Thus the feed may be regulated to suit the character of the ground being drilled, and when starting a hole, crossing a slip, or cutting through a vug or soft place, the operator can so manipulate the action of the drill as to prevent its becoming stuck, and use just the right kind of blow. These changes of operation are controlled by a common throttle-valve which admits air to both ports of the feed, and to the drill as required. The runner does not have

THE NEW AIR-FEED HAMMER-DRILL.

to stand behind his machine in order to operate it, but can stand in front, with both hands directing the steel after the throttle has been set in the desired position.

For changing steels, the reverse-feed pulls the drill back with the steel instantaneously. The complete operation of pulling back, changing steels, and running up to the face with a fresh steel, should not take over 30 seconds.

The pneumatic feed, in combination with the Sullivan rotator, makes a machine that is practically an all-around drilling tool. The drill itself weighs 40 lb., and the pneumatic-feed cylinder and piston, with offset arm, 65 lb., so that the outfit can be handled readily by one man and carried by him into inaccessible parts of the mine. It is a popular machine with lessees at small mines, as it can be used for shaft-sinking, cross-cutting, and stoping, with minimum expense and delay.

EDITORIAL

T. A. RICKARD, Editor

TUNGSTEN is in great demand. In this issue we publish letters from our local correspondents in several mining districts describing the search for this useful metal.

CLOSING of the Panama Canal is unfortunate for the American Smelting & Refining Company's new tin smelter at Perth Amboy, New Jersey. This plant, designed to treat Bolivian tin concentrate, is nearly ready to start. It will not be the first tin smelter built in the United States, but it will be the first to produce tin.

THOMAS W. LAWSON is on the war-path again. Woe to the mine that he dishonors with his attention. Just now he is boosting Alaska Gold Mines, which needs no inflation. In a recent 'tissue' he says that the stock "will probably fly over $50 and $60, and to $75 as soon as what's doing now is done." This sort of talk serves only to discredit a splendid mining enterprise.

ONE of the features of the Exposition has been the nomination of individuals as "the most distinguished citizen" of the respective states. Arizona, by its Governor, selected Mr. L. D. Ricketts as its representative; whereupon he was the victim of a luncheon and a plaque on November 18. It is proper that a copper metallurgist should have been selected and it will please Dr. Ricketts' many friends that he should be honored thus in Arizona and California, but the president-elect of the American Institute of Mining Engineers will not modify his geniality with hauteur on that account. We referred to his nomination as President in our issue of September 25. The news of it has been received with keen pleasure throughout the ranks of the profession.

MOVEMENTS of mining engineers, recorded weekly on another page, indicate that several experienced members of the profession have visited Oatman lately. One of them, Mr. J. Parke Channing, expressed a good opinion of the district in a published interview; at least, he spoke highly of the United Eastern mine. In our issue of July 31 we published an article by Mr. Howard D. Smith on the principal developments and the general character of the district. We hope shortly to supplement that article with another. Meanwhile the daily press is being subventioned by promoters for the purpose of publishing grandiose statements concerning individual prospects in this promising gold-mining district. Such newspaper talk, we trust, will do no particular harm. Real work is being done on a great number of claims, one or two of which may prove to be veritable gold mines, like the Gold Road, Tom Reed, and United Eastern. The story appears to be authentic that the richest mine at Oatman, namely, the United Eastern, was discovered in consequence of scientific inference from evidence noticed by Mr. G. W. Long while working as a miner in the Tom Reed. He noticed that the succession of ore-shoots in the vein ceased westward and the idea came to him that the line of enrichment might follow what appeared in the level as a branch vein northward. By aid of a Brunton compass he obtained all the necessary data for 'locating himself' on the surface. Having obtained this information he went to Bisbee and consulted his friend, Mr. J. L. McIver, then shift-boss in the Copper Queen. They joined forces, returned to Oatman, bonded the claim that covered the supposed extension, sank a shaft, and struck a vein, finally, with the financial assistance of Mr. Seeley W. Mudd, developing a notable mine. The story is worthy of record as an example of the successful application of economic geology. Of course, Mr. Long will demur to the use of either 'scientific' or 'geologic' in connection with his fortunate experience, but, as a matter of plain fact, the putting of two and two together, the careful observation and the intelligent reasoning, constitute the very essentials of scientific work. Science, said Huxley, is organized common sense. It is common sense glorified to maximum efficiency. The result in this case is that Messrs. Long and McIver are part-owners of a well-organized bonanza in the sunny state of Arizona.

ELECTROLYTIC ZINC is being made at Anaconda on a working scale, namely, 10 tons per day. It is presumed that a large plant for the extraction of zinc by this method will be erected at Great Falls, but the management is reticent, pending further investigations. Cheap electricity and suitable ores are both plentiful in Montana, not to mention the highly favorable market for the metal now available. The zinc produced by this process makes the highest-grade spelter, free from impurities, such as cadmium, lead, and iron. Such spelter is in particular demand for the manufacture of brass in cartridges. Another effort, approaching success, to treat zinc ore by electrolytic precipitation is the Reed process, of which we gave a description in our issue of January 2.

SINCE the First Chief of the Constitutionalist party was recognized as the head of a *de facto* government in Mexico, we have been waiting for him to establish his authority by scattering Villa's forces and driving Don Pancho across the Rio Grande into permanent exile. Mining companies in this country are not disposed to hasten a resumption of business until Carranza makes some definite statement as to the treatment they may expect under his governance. His decree of last March

has been modified for the present, but it is intimated that he intends to impose the full force of punitive taxation next year. Railway traffic is terribly disorganized; although we have reports of trains running with several changes between Laredo and Mexico City, the supply of rolling stock is so scanty that if the mines and smelters were to resume even on half-scale the ordinary freight and passenger service would be insufficient. Not enough rolling stock survives on the National lines to handle more than a fifth of the usual business, and even this remnant is in bad repair. Recent comers from Mexico City report that the rolling stock of the Vera Cruz line is badly demoralized, as well as that of the railways farther south. Travel from the capital is largely effected on box-cars. The number of engines fit for use has been reduced to a dozen. Carranza, instead of being able to get supplies in large quantity, as he had intimated, has been unable to move foodstuffs or supplies more than a small part of the way. In the North, an attempt was made by Villa to take possession of the smelter at Chihuahua and to operate the plant, but the task was too much for the *revollosos*. An effort was actually made to start work with a little wood and coke, but it failed. After much bluffing the smelter was left uninjured. A few mines continue development work, and the Alvarado mill is still being operated. The American Smelting & Refining Company has made no attempt to resume work at any of its smelters, as it is necessary to have transport assured both for fuel inward and bullion outward, besides a steady supply of ore and flux. This company is not in a hurry to resume operations that have yielded only a small and precarious profit during the past twelve months. Cananea has suffered from changes of control. According to the last news, Villa had captured two American doctors and compelled Dr. L. D. Ricketts to pay him $25,000 in ransom. That performance is humorous as compared with the other spoilations and brutalities for which Villa is personally responsible.

Electricity in Flotation

Theories explaining flotation are undergoing development in the wake of mill-practice and laboratory-experiment. In this issue we publish a timely article on the electro-static theory as it appears to Mr. Thomas M. Bains, Jr., an assistant-professor in the Sase School of Applied Science, at Cleveland. The idea of electricity as a factor in flotation has been suggested recently in several articles published in the Mining and Scientific Press, notably in 'Why do Minerals Float?' by Mr Oliver C. Ralston, under date of October 23, in which credit is given to Mr. J. M. Callow for initiating experiments by Mr. R. C. Bacon at the Mellon Institute of Pittsburg. We may add that Mr. Callow read a paper bearing on the subject before the Salt Lake section of the American Institute of Mining Engineers early in October. This paper, when released for publication, will be printed by us without delay. Meanwhile our readers will thank Mr. Bains for his timely contribution to current knowledge. His statement of the case is to the point and gives the essentials with admirable lucidity. The electrification of the bubbles, by the friction incidental to agitation or movement through the pulp, serves to render them attractive to the metals and metallic sulphides, so that the latter become attached to the bubbles, which buoy them to the surface. The insulating film of oil serves to prevent the electric charge from becoming dissipated, and thereby breaking the froth, until it has done its duty as a conveyor of the mineral. We are also given an explanation of the function of acid in a flotation pulp, namely, that it increases the conductivity of the pulp and hastens the discharge of electricity on the particles of gangue. Of course, the older idea, utilized in the De Bavay process, that the acid dissolves an oxidized crust on the sulphides is not contradictory, for the cleaning of the metallic surface would expedite electrification. Similarly the notion that the acid promotes the wetting of the gangue is compatible with this later theory, for the 'wetting' supplies an insulating envelope. However, we shall leave the further discussion of the subject until we have given our readers the paper by Mr. Callow, to which reference has been made. It is worth noting, incidentally, that the electrical theory was not introduced into the arguments presented in the course of recent patent litigation.

Early Days in Colorado

In this issue we publish some technical reminiscences of Mr. David W. Brunton, covering his first experience in Colorado and Montana. The subject and the author join in making this article unusually interesting. Mr. Brunton is one of a small group of capable Canadians that have enriched the profession of mining engineering in America. While his preliminary instruction was obtained at Toronto, he owed his first step as a practitioner to the University of Michigan, as he tells us on another page. As an ex-President of the American Institute of Mining Engineers he obtained official acknowledgment of his distinction in engineering many years after those of us who lived in the West had learned to recognize in him one of the ablest and most honorable exponents of a difficult calling. The inventor of a surveyor's compass now in use in every quarter of the earth, he possessed that magnetic needle of character which guided him through the shoals of circumstance to a foremost place in the roster of the profession. Indeed, we are glad to publish these recollections of his early work, knowing well that hundreds of his old friends will read them with keen pleasure, while an even larger number of younger men will find in them a suggestion and a stimulus to honorable endeavor.

His story of the trip to Mineral Point in 1875 appeals to the present writer because it travels over familiar trails. Mineral Point has never fulfilled the hopes of the prospector. Situated on a ridge separating the headwaters of the Animas and Uncompahgre rivers, in the very heart of a great mineral region, it has belied the expectations of many experienced men. The andesitic

mountain sides are seamed with veins, the outcrops of which can be seen from afar as white lines of remarkable continuity. The Point itself is a knob of quartz fully 60 feet thick, from which several veins diverge, as if it were a centre of mineralization—which is just what the early prospectors assumed it to be. Mr. Brunton missed nothing by not camping there longer than he did. On his way thither he 'struck it rich' in meeting Mr. H. W. Reed, who, in later years, became connected professionally with some of the richest mines in the San Juan, notably, the Virginius. Mr. Reed lives now at Salt Lake City, as is shown by the vigorous letters he wrote in our issues of July 24 and August 14 on forestry anomalies. On his way out, Mr. Brunton descended Henson creek, passing the Ute and Ulay silver-lead mines, which, for a decade, at least, were the main support of Lake City. When he tramped up the Lake Fork of the Gunnison, he must have left the valley near Lake San Cristobal, where Enos T. Hotchkiss had started the diggings that became the celebrated Golden Fleece mine, which, in 1896, shipped nine carloads of ore averaging $40,000 per ton, and in a few months yielded a fortune to Mr. George W. Peirce, who is now at Oatman, Arizona. In following the Rio Grande valley to Del Norte, Mr. Brunton must have passed the place where 16 years later Creede sprang into life and joined with Cripple Creek in saving Colorado during the dark days of 1893. According to recent reports this district, which came to the front with N. C. Creede's discovery of the Amethyst vein in 1891, is still far from dead, even if it is not quite so ebullient as in the days when Cy Warman sang:

> "It's day all day in the day-time
> And there is no night in Creede."

How Denver looked in the period to which Mr. Brunton refers is shown by the accompanying photograph of an old wood-cut now in the possession of the Historical Museum at Denver. Forty years is no great lapse of time, as measured by the historian, but to the eager exploiters of the Great West it is as a geologic period. In those Eocene mornings of 1875 Mr. Brunton found Central City and Georgetown in the throes of metallurgical revolution. The free-milling precious-metal ores of the oxidized zone had been succeeded, at a shallow depth, by heavily pyritic and relatively complex ores. Roasting before pan-amalgamation and hyposulphite leaching had brought the Brückner, Küstel, and Stetefeldt furnaces into prominence. The Collom jig had just been invented; but concentration was crude. N. P. Hill had established his smelter at Black Hawk, and had just been joined by Mr. Richard Pearce, now living near Liverpool, in England, after a long career of useful accomplishment. The Stewart mentioned by Mr. Brunton was J. O. Stewart, who had an important custom-mill at Georgetown. He had built an annex for the application of the Hunt & Douglas process, a method lending itself to graphic representation by the chemical formulæ that used to bother many of us in our student days. The process is now obsolete, but the names of the two inventors live in the annals of mining, for Thomas Sterry Hunt gave to chemical geology many provocative suggestions and Mr. James Douglas has lived to be one of the most beloved of men, known the world over for his skill as a metallurgist, his sagacity as an executive, and his public spirit as a citizen.

Coming to the Leadville reminiscences of our distinguished contributor, we may be permitted to say that the talented author of 'The Led Horse Claim' attended the recent meeting of the American Institute in San Francisco, being the wife of one of the leaders of our profession, Mr. Arthur DeW. Foote, long identified with the successful operations of the North Star mine at Grass Valley. In regard to the Van Zant story, the present writer arrived at the Blue Bird mine on the very morning when the news of his suicide reached William Keller and Mr. Philip L. Foster, the latter now resident at New York as the representative of the Exploration Company. The former died a few years later at El Oro. Austin H. Brown was then in charge of the big mill; he died in 1913. Mr. Charles Van Zant was also at the Blue Bird on that date, in 1891; he called at this office a few weeks ago. The Blue Bird has played a part in the lives of a great many notable men, as is shown by Mr. Brunton's notes concerning the early litigation at Butte. Those apex-suits still proceed with undiminished keenness and continue to furnish a grindstone for sharpening the wits of men mentally alert to the niceties of structural geology. Our readers will like Mr. Brunton's account of his own part in them, and they will appreciate the letter from Mark Twain to H. H. Rogers. Truly, "virtue, as well as ballast" is required for a safe voyage to any port in life. The strength of purpose and continuity of effort that give direction to human endeavor are shown in the auto-biographic records of our successful engineers. In the days of their apprenticeship to the profession, they applied themselves with sincerity of aim to the acquirement of knowledge and experience, accumulating a mental capital that yielded generous dividends when subsequently opportunity knocked on their door.

American Potash

In our issue of August 7 we reviewed the prospects of a domestic supply of potash and referred to the alunite deposits of Utah as being of great promise. That promise apparently is to be fulfilled. Actual production has begun. A shipment of potash was made in October, the first carload being consigned to Florida. It averaged 93% sulphate of potash. The scene of this new and important industry is Marysvale in Cottonwood canyon, at the foot of the Tushar range, and about six miles from the Denver & Rio Grande railroad. The deposit consists of a series of long lenses of pinkish-white alunite, outcropping on the mountainside, now penetrated by adits, from which the mineral is conveyed by aerial tram to the bottom of the valley. This lode of pink spar in andesite has been a disappointment to many prospectors, who had tested it for various metals, particularly gold. It was generally called heavy spar or barite. Some local

quidnuncs said it was wavellite. An assayer at Salt Lake City, Mr. A. E. Custer, was the first to suspect its real value, finding a high percentage of alumina; finally a specimen sent to the Foote Mineral Company at Philadelphia was returned with the correct label: alunite. The mineral contains 10 to 12% potash, 34 to 37% alumina, 13% water, and 36 to 38% sulphur tri-oxide. In Bulletin No. 511 of the U. S. Geological Survey, issued in 1911, this deposit at Marysvale was mentioned as "an important deposit of alunite," containing both potash and aluminum. In the same bulletin it was stated that the potash was soluble; but no workable process had been devised at that time. A group of men associated with Mr. J. Ogden Armour had obtained control and exploratory work had been started under the direction of Mr. Howard F. Chappell when the War cut off German supplies of potash, sending the price in this country from $50 to about $300 per ton. That, of course, offered an inducement to go ahead with the enterprise. Experiments finally have proved that careful roasting in a rotary kiln expels the sulphur, leaving a pulverulent product from which the potash can be dissolved with hot water, while the insoluble alumina remains in the residue when the two products are separated by a filter-press, the solution passing to vacuum-pans where boiling followed by evaporation yields a crystalline residue of sulphate of potash, which is then dried, pulverized, screened, and sacked for shipment. The first unit of plant has a capacity of 25 tons of such potash per day. The undigested aluminous residue obtained in the course of this treatment may become a valuable by-product, as a source of metallic aluminum; indeed, it is difficult to say which of the two, the potash or the aluminum, will prove the more valuable. Just now the demand for the former is so great that it is the more attractive; in normal times the yield from both will be required to ensure a profit. While the Armour Fertilizer Company is represented in the directorate, we note that Mr. Sidney J. Jennings, of the United States Mining, Smelting & Refining Company is a vice-president, Mr. Chappell, an experienced chemist and the prime mover in the enterprise, being president of the company, which is called the Mineral Products Corporation. Obviously there is no lack of money, ability, and technical knowledge. The deposit mentioned is only one of several in the same locality; other outcrops have been traced; and numerous attempts to exploit them are now assured. All of them are on unpatented lands, so that the question of title may check development, until the Federal Government has explained its policy.

Meanwhile there comes good news concerning Searles Lake, in San Bernardino county, southern California, where, as most of our readers are aware, a big saline deposit is being exploited for potash by the American Trona Corporation, a company in which the Consolidated Gold Fields of South Africa holds a large, but minority, interest. A railway 30 miles long has been built from the site of the deposit to the Southern Pacific railway at Searles, and a refinery is now being erected at San Pedro, on the coast. For two years this enterprise has hung fire, owing to difficulties in the extraction of the valuable salts. The dry lake contains a concentration of brine, estimated at 60 feet thick over 11 square miles, containing an average of 6½% potash, equivalent to 10% potassium chloride. A 10-inch pipe-line is now being constructed to convey the brine from the lake to the concentrating plant at Trona, where the water is evaporated. The potash and borax become concentrated in a product that is shipped to San Pedro, where the valuable salts are separated and refined before shipment. It was ascertained that the pumping of the brine direct from the lake to tide-water was impracticable, on account of the cost of the required piping; hence the decision to concentrate the valuable salts at one plant and to separate and refine them at another. The process adopted, under the direction of Mr. C. P. Grimwood, involves fractional crystallization in tripple-effect vacuum-pans, removing both the chloride and the sulphate of sodium at the Trona plant, thus leaving residuum that will yield potassium chloride and sodium tetra-borate at the San Pedro refinery. When pure the potassium chloride will sell for $300 per ton, but a lower-grade salt is used in the fertilizer industry. As for the borax, there is no trouble in finding a market. It is expected that both potash and borax will be produced by the Trona Corporation not later than April next.

Many references have been made recently, in the non-technical press, to the winning of potash from kelp or sea-weed. This can be done by drying and grinding the kelp, yielding a product that contains 10 to 13% potash and resembles in composition the kainit of the Stassfurt deposits. However, no contribution of potash from such a source is within sight, despite several attempts. From consular reports it appears that the use of kelp as a fertilizer has been much stimulated in Scotland since the War began; it is also an old industry along the French coast, and particularly in the Scilly Isles, off Cornwall, where it is used in truck-gardening to the extent of 40 tons of sea-weed per acre. But, at present, this source of fertilization is of no consequence as compared with the mineral deposits mentioned.

The importance of these efforts to produce potash salts is clearly indicated by the statistical evidence. In 1913, the latest normal year, the United States imported 306,000 tons of potash, worth $10,800,000, of which $7,000,000 represented potassium chloride and $1,700,000 potassium sulphate. These figures do not include fertilizer salts. Speaking broadly, the carbonate is used in glass-making, the cyanide in metallurgy, the nitrate in the manufacture of explosives, the sulphate and the chloride in the fertilizer industry. As indicated above, 80% of the potash imported is intended to aid agriculture. In 1914 the sulphate was worth $41 and the chloride, which contains less potash (K_2O), sold at $33 per ton. The War not only stopped shipments but an embargo on the export of potash salts was promulgated by the German government at the end of January 1915. Hence the potash famine in this country and the keen interest awakened by the work now in progress, both in Utah and California.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mining Engineer and Prospector

The Editor:

Sir—I have read with interest the various letters recently appearing in your magazine on the relation of mining engineers and prospectors to mining development. The subject is not only interesting but serious. A healthy activity in mining calls for not only the development of prospects but also the continued exploration of old mines and old districts.

Anyone who has had opportunity to spend some time in the mountains of the Western states will realize that of the prospects the vast majority are worthless, judging from what we know of geology and the theory of ore deposits. There are, however, a goodly number that deserve to have money spent on them, although in many of these cases he who spends the money may never get it back. The persevering, optimistic, and intelligent prospector has been the greatest factor in the development of the mining industry and there are still some of them left, although probably outnumbered by men less dependable. The chances for the prospector without capital are becoming less and less, and the future prospecting will have to be done with the diamond-drill or by powder and fuse in large quantities. One of your correspondents quotes the head of one of the large exploration companies as saying that it is difficult to see where the big mines of the future are coming from; this is liable to be the attitude of a mining man after he has been in the office for a while reading the adverse reports of competent engineers who have been sent out to look at the great mines discovered by a pseudo-prospector and promoted by a pseudo-promoter. When, however, a mining man gets on his hobnailed boots and gets a little closer to nature he usually sees many places where some thousands of dollars judiciously spent might make another big mine.

Far more plentiful than prospects, also, are mines that have once produced but are now idle, or that are quite extensively developed but have produced very little or nothing. Many of these show all the ear-marks of good properties but seldom is there any ore available. It takes money to go in and find ore and that money may be lost. Mining is not a sure thing, and the mining engineer who waits for a dead-sure thing to recommend is liable to wait a long while. On the other hand, those who keep at it and use the best mining judgment they can get, spending money on first one thing and then another, usually win out. On a sure thing one cannot expect more than 4 to 6% on money, but in mining there is no limit. The sooner the public (and mining engineers, too) come to the proper realization that mining is a man's game in which money may return enormous profits or may be lost, and the public demands a judicious expenditure of the money that is invested, just that much sooner will mining be in a healthy condition.

CARL A. ALLEN.

Denver, November 4.

The Prospector

The Editor:

Sir—Under the above heading in your issue of October 16, Mr. Ernest G. Locke replies to mine of September 18. His reply indicates the effect I intended, that of caving the ground and relieving the prospector from the overburden of the hostile engineer and press. Mr. Locke has drawn a faithful life-size portrait of the average mining engineer. That Mr. Locke, when examining a prospect, brings into action the same care, skill, and experience that he would give to a developed mine, speaks well for his methods—more power to him. But why inject into a report so much caution; are geological conditions always unfavorable to a prospect becoming a successful venture? If a man's training enables him to value conditions accurately, why not state the value of what is seen? It may be because the mining engineer is none too sure of understanding the local conditions that he hesitates to recommend a prospect. My own view-point takes in the field not only as a prospector but as a responsible adviser to a critical investor, a position aimed at since 1880 when I was in Rhodesia.

My interest and sympathies will always be with the prospector; to show that he is regarded as an unimportant element in the mining field, I will cite an experience of my own. After years of hard work, my feet finally landed on the pay-shoot and it was not difficult to show a clean clear profit to the investor. My spirits rose as he remarked. "Now Mr. W., I find that you have a very interesting proposition; you have quite a little ore developed of good grade and some on the dumps. I like the appearance of your orebodies and the facilities generally. Now, what do you ask for the property?" I outlined a scheme of payments thus: nothing down, first payment in six months, the remainder of price to be paid thereafter in three installments of six months interval, a royalty of 10% to be paid on all ore milled and to apply on final payment. Could anything be fairer? Did I sell? Wait and see. "Now Mr. W., will you give me an option on it for 60 days?" "No sir." "Very well. I should

like our Mr. So-and-So to see it." "All right." After many days, Mr. So-and-So arrived; instead of an associate investor, he was from boots to eyebrows relentlessly and irrevocably a mining engineer, very anxious to get back to the office. With a jaunty debonair air, he wished to be shown the vein. I handed him a short piece of candle; I knew that would be enough. He took three samples, and concluded his labors in 30 minutes. To examine a prospect in 30 minutes is about what I expected from an office product. Of course nothing escaped his lightning survey. It was a prospect; that settled it. His faculty for careful appraisal was atrophied by comfortable conditions in an office. He could not afford to risk his position by recommending a prospect, because his value to the firm is measured, not by the amount he makes for them, but by the amount he saves them. Also his limitations are fixed by training, his horizon is so bounded by caution—extreme caution—that imagination is quenched and he falls to the level of a notary-public. Such men as J. F. Kemp or J. E. Spurr, never balk at analysis of conditions. The logic with which they trace a mineral and its carrier to its final deposition wins the prospector, because he knows whenever investigation is started by them, or any other conscientious engineer, they lose sight of the owner and investor. The prospector knows that patient investigation is in progress and has no kick to make if the verdict is against him. If I were a mining engineer, which I wish I was, and called to pass on a prospect, I'd forget the office, and concentrate whatever ability I possessed on giving the prospect or mine a fair shake.

The Mechanical Efficiency of Crushing

The Editor:

Sir—It appears to me that instead of Mr. Stadler casting insinuations in respect to one's sanity and displaying utter contempt for those who do not agree with him in the application of Kick's law of crushing, he might enlighten us with some of his own experiments, proving his contention. It may be that I have overlooked some of his writings on the subject and therefore have not seen his practical proofs. Mr. Gates has had the advantage of a well-equipped laboratory (as I understand) and he is a qualified expert (I believe) and yet his results differ from those obtained by Mr. Stadler's authorities of "half a century ago." Mr. Stadler must know that problems settled half a century ago are being unsettled every day, so this argument has little weight. Because some of us have not the use of well-equipped laboratories there is no reason why we should accept conventional theories when simple experiments prove that the experts may have overlooked something. It is poor argument to first cast personal reflections and then try to thrust your argument down the other fellow's throat, better to treat the other as a human being and then try to convince him of his mistake. It has been generally understood that the Mines Trial Committee of South Africa took this subject in hand, likewise that a full report of the result of the investigations was not made public. I hope I am wrong in this, but I have read that such was the case in one of the technical journals. If this is as represented, will Mr. Stadler procure and give to the public the results of these investigations? In my opinion this will be more to the point than proving an opponent to be a weakling and then saying "I myself am only sane." It is generally understood that inventors, poets, and musicians have a touch of insanity and as these offsprings of the human race have an acknowledged place in the economy of creation so possibly may those who kick at "Stadler's theory" as you, Mr. Editor, so well designate it. What is needed is argument, new ideas, encouragement to investigate, something that is not final; in fact, we must have argument and publicity to promote the slightest interest in a subject, but not personalities. I am quoting from memory but I believe Mr. Stadler has stated that the comparative efficiency of stamps and tube-mills on the Rand varied as 70:17 or 4:1. Any practical operator knows that this is not so in respect of tube-mills in other localities, so we must assume that either tube-milling on the Rand is little understood or Kick's law is out of joint somewhere. The argument may come back that by the Rittinger theory the relative efficiency of stamps and tube-mills under like conditions closely approximates this result. No doubt it does, which clearly indicates that the subject is still open for investigation, that there is a possibility of both theories being far from true and that a crank may find the right answer.

While I feel greatly flattered that on mature consideration by Mr. Stadler my remarks were worthy of a reply I can assure him that had he passed me over I would not have been offended. I can also assure him that his method of attack has not helped his cause, on the contrary to some it may appear that when a scientific man gives way to personalities in argument his cause needs first-aid.

Algernon Del Mar.

Los Angeles, November 9.

Moving Machinery

The Editor:

Sir—I believe many mine superintendents, and perhaps, also some engineers, will be interested in a series of contributions from others on the subject of moving heavy pieces of machinery, such as are usually part of the equipment of mines and metallurgical works. The foundries and shops, where boilers, engines, mortars, crushers, and other heavy machinery is made and assembled, are usually equipped with electrically-operated cranes by means of which pieces of machinery weighing many tons are picked up at one place and set down in another with the greatest ease, by two or three men. These machines, when ready for shipment, are lifted on board of a railroad-car, which is run into the shops and sent away on its long journey to mines, often hundreds and even thousands of miles distant from the place of

manufacture. When this machinery arrives at the station on the railroad nearest the mine, there may, or there may not, be available a crane or derrick by aid of which the machinery may be moved from the railroad-car to the depôt platform, or even to place it on the freight-wagon on which it is to be hauled to the mine, which may be many miles distant in the mountains.

But, on arrival at the mine, there is no electrically-operated traveling crane—not even a shears or derrick—with which to lift and move the heavy machine from the wagon to the ground, or onto a crib of timbers, to say nothing of placing it in its permanent position on the foundation prepared for it. At such isolated mines, particularly the small ones, about the only things usually available for such a purpose are timbers of various sizes, wedges, ropes, pipes in short pieces for use as rollers, planks, and crow-bars. At a few mines there may be found 'jacks' of one kind or another, though too often these very useful adjuncts are missing; but there are few mines that do not possess one or more sets of chain-blocks.

The problem upon which I desire enlightenment is the methods generally employed in shifting heavy machines from one position to another with no other mechanical implements other than those mentioned in the last paragraph, in order that the best methods be selected from any that may be offered. To me it seems that the department of your paper devoted to 'Discussion' is the best place in which to seek the desired information.

I am sure there are many who have had just such problems in their pioneering experience, and have found a way out of the difficulty, and there are as many more who would be most grateful for any suggestions made by those who will contribute something to this subject from their experience along these lines. As I do not wish something for nothing, I am willing to set an "excellent example" by describing the means I employed to set a heavy oil-wagon equipped with a 1200-gallon steel tank on its feet after it had been carelessly driven off the grade and overturned by a teamster, where it lay on its side four feet below the level of the roadway, a mile from the mine.

The great wagon with its tank weighed several tons, but fortunately was empty. When I first saw it lying there below the road in a position where it might easily roll over a few times more, thus continuing its journey down the mountain, it presented anything but a pleasant prospect for the early resumption of usefulness. It was absolutely necessary to get that wagon back on the road at the earliest possible moment, or the fuel-supply would be shut off, and this meant the closing-down of the works. It was cheaper to get the wagon back on the road.

I took about a dozen men; twenty pieces of 6 by 6-inch timber, mostly posts and caps of drift-sets already framed and ready to hand in the yard; a coil of 100 ft. of 1-inch manila rope; a two-ton chain-block; several crow-bars; two jack-screws; a piece of 8 by 8-in. timber 12 ft. long; a piece of ⅜-in. steel rope picked up in the timber-yard, and two or three pieces of inch-rope each 12 or 15 ft. long: also picks and shovels for the entire crew, with a rock hammer or two. This equipment was such as can be picked up around any mine in a few minutes. The whole outfit was placed in a wagon and started for the scene of the accident as quickly as possible. The men took a trail over the hill, all arriving about the same time. At once I set two men at work digging a hole on the upper side of the road opposite the overturned wagon and about 20 ft. from it. This hole was sunk to a depth of about 4 ft. and was kept as small as possible. When it had reached this depth the piece of 8 by 8-in. timber was placed upright in the hole and the rocks and dirt filled in around it, the fill being tamped as firmly as possible. The post was inclined backward at about 70° from the horizontal. To render this post more secure I had an inch-steel bar driven in the ground to the depth of several feet at a point 10 or 12 ft. back from the post. The little steel rope was now made fast near the top of the post and the other end was wrapped around the steel bar driven into the ground. Meanwhile, two men had placed the long manila rope about the tank and the wagon in the form of a sling, the rope being secured so that it could not slip. The several pieces of framed timber were placed on the ground near the wagon, to be used in building a crib beneath the wagon when it was lifted by means of the chain-blocks, for it was evident that the wagon could not be placed upright without running out the chains at least twice, and the crib of timbers would hold the wagon in position while the blocks were being changed. The men not otherwise employed were set at work grading from the position of the wagon up to the roadway, so that the wagon could be hauled back upon the road without the danger of again overturning when once more upon its feet.

When the 'dead-man' had been firmly set in the ground and further secured by means of the steel bar and little steel rope, a short sling, made from one of the pieces of manila rope, was thrown around the dead-man, well-down, and the chain-blocks placed in position, being hooked into this short sling at one end and into the large sling around the wagon at the other. When all was in readiness, three men began to work at the chains of the blocks. A great deal of slack and stretch of the rope had first to be taken up, and but little impression was at first made on the wagon, but at this juncture a piece of 6 by 6-in. timber about 7 ft. long was placed on end under the rope-sling, one end resting on the ground, the other end being against the rope. This timber was inclined toward the wagon at an angle of about 40° from the horizontal. The effect of this device was to give a more direct lift to the sling, and its effect on the wagon was promptly noticed, for as the men pulled on the chains, the sling-rope binding on the end of the timber, began to lift the wagon and in a short time we were able to begin placing the timbers beneath the wagon as it continued to rise, thus supporting it in position while the blocks were run out again. In a few minutes more the heavy vehicle was lifted to a point where it once more passed its centre of gravity (on the proper side, this time). The grading having been completed in the meantime, the team was

hitched to the wagon once more and quickly left for the railroad to get another load of oil, as fortunately nothing was broken by its fall. The whole matter of lifting this great wagon and getting it out of the way did not take more than 45 minutes. The roadway was repaired and widened at this place, though it really did not require it. The careless teamster was one of the best in the country, having passed this turn in the road in safety a thousand times during several years in this service, but, like some other good men, he became a little careless, and dumped his wagon into the ditch, springing from his wheel-mule just in time to escape injury himself.

W. H. Storms.

Berkeley, October 24.

Mine Accidents

The Editor:

Sir—Accepting the invitation in your issue of October 9 to discuss the question of accidents in mines and their causes, I offer for consideration the following statistics of fatal accidents or casualties in the mines of Houghton county, Michigan, for the year ending September 30, 1915. The mines in which fatal accidents occurred during the year in question are the Quincy, Champion, Trimountain, Baltic, Hecla Branch, South Hecla Branch, Calumet, Red Jacket Shaft, Isle Royale, Superior, Centennial, and Hecla Amygdaloid.

With a total of 16,005 men employed, only 34 casualties occurred, showing a proportion of casualties of 0.0021. Classifying the fatalities according to occupation, we have 11 miners, 6 timber-men, 10 trammers, 3 track-men, one shift-boss, one shaft-boss, one sprinkler, and one roller-fixer, and according to nature of accident: falls of rock 24, struck by skip 4, struck by timber 2, drilled into missed hole 1, fell in chute 1, fell off skip 1, and struck by car 1.

I have read carefully the testimony of witnesses and the verdict of the jury in each of the 34 cases, as stated in the county mine-inspector's report. In only 8 cases out of the total of 34 can the accident be clearly attributed to carelessness on the part of the men killed. Four of these were cases of men being struck by the skip; one case was that of a man who fell off the skip; in another case the man fell in a chute; in another a miner drilled into a missed hole. Only one case of fall of rock can be stated as due to carelessness. In these 8 cases of apparent carelessness only 2 miners were killed, the others being timber-men, trammers, and men doing minor jobs underground.

Accidents from fall of rock appear to be the most numerous, 24 of the 34 being of this nature. The question then is, are these falls of rock due to carelessness on the part of the men? In 9 of these 24 cases miners were killed and in 2 other cases a shift-boss and a shaft-boss were the unfortunate ones. All of these men were probably experienced underground men. In 10 of these cases the verdict of the jury was that death was caused by the accidental falling of loose rock. In nearly all of the 24 cases witnesses stated that the ground looked perfectly safe, in many cases had actually been tested, and that they were willing to work in those places where the accidents occurred. In two of the cases considered under 'fall of rock' death was due to pneumonia indirectly caused by injuries.

Since some may question my ability to judge properly a case of fall of rock, let us consider one or two cases in detail. Capt. William Jolly and Supt. Mendelsohn went into the 17th south stope on Wednesday April 28, and found a miner back about 12 ft. from the breast, which he had just drilled. No blasting had been done since the Thursday previous. Mr. Jolly called the miner and told him to bar down some loose rock. The miner could see no reason for doing this, since no one was working there. However, Mr. Jolly told him to bar it down anyway. Mr. Jolly then walked toward the hanging, when some rock fell causing his death. The jury rendered a verdict of accidental death.

Capt. John Mitchell walked up the stope to where some men were charging holes. Witnesses stated that they had walked up and down in the same place all day. Mr. Mitchell had just asked the men how they were getting along when a piece fell from the hanging, causing his death. The jury reported "that Capt. John Mitchell came to his death by an accidental fall of rock while attending to his duties."

Consider the case of Jim Nuceetti, a miner, drilling a hole with a machine. A fall of loose dirt from above caused him to fall over the stope. John Dutich was struck by a piece of falling timber, which probably fell from the front of the skip-catcher. Witnesses stated that 20 or 30 air-shocks occurred, and these might have shaken the piece of wood off. In another case a miner was killed by a fall of rock due to an air-blast. Can these deaths be attributed to carelessness on the part of the men?

Let us now consider one or two cases of a different nature. In the case of the man who felt so fine that he sang all night while cleaning down the shaft and finally fell off the lip of the skip we have reason for assigning his death to carelessness.

Joe Nanfil was struck by a piece of hanging rock after he had been repeatedly warned not to go in the shaft while the timber-men were working in the shaft. This too appears to be a case of carelessness.

Stanislaw Sichlucki came to his death by falling in a chute after having had strict orders prohibiting him or any one else from going there.

Whether the death of Otto Hess, caused by an explosion resulting from his drilling into a missed hole which had powder in the bottom, can be attributed to carelessness is a question. However, I have so considered it.

The records and statistics that I examined prove, in my opinion, that the majority of deaths in the mines of Houghton county during the year ending September 30, 1915, were not due to carelessness of the men killed.

W. E. Hopper.

Houghton, Mich., November 10.

Technical Reminiscences

By D. W. BRUNTON

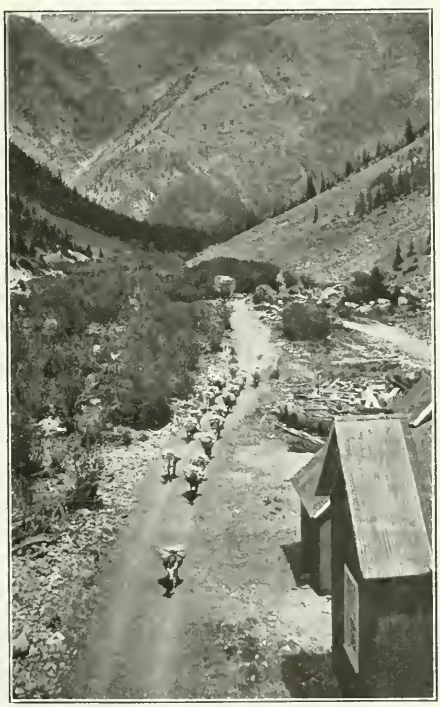
Early in June 1875, Major C. H. McIntyre, president of the Dakota & San Juan Mining Co., came to Ann Arbor, Michigan, to see if he could engage a young mining engineer to go out to Colorado with him to take charge of the engineering department of his newly organized mining company.

As I had been taking a special course at the University of Michigan, some of the faculty were kind enough to recommend me for the position, which I needed fully as much as the Dakota & San Juan Mining Co. required an engineer. Arrangements were speedily concluded and we immediately started for the West, arriving in Denver on June 20. The trip from Chicago west at that time was far from being as comfortable as it is today, but it was enlivened by the sight of countless herds of buffalo, which were still roaming over the plains almost unmolested.

At that time the American House on the corner of 16th and Blake streets was not only the leading hotel of the city, but was situated practically in the centre of the business district. What is now the business centre of Denver was at that time the residence district, and the present fashionable residence portion of Denver was then densely populated by prairie-dogs. Three or four years later, when Major McIntyre decided to make Denver his home, he bought a house away out in the country where, as he expected, he would always have an entirely unobstructed view of the mountains. This residence has lately been pulled down and its site occupied by the Bank Apartment house, 1233 Sherman avenue. Mining and the passing years have both dealt kindly with the Major as he is now 'on Easy street,' hale and hearty at the age of 78.

We remained in Denver over a week, engaging a force of miners and purchasing mining supplies, and on the morning of the 29th left for Pueblo over the Denver & Rio Grande, which was at that time a narrow-gauge railroad. To test our camp equipment and to make sure that we had everything necessary for the long trip from Pueblo to Mineral Point, in the San Juan, where the Dakota & San Juan Co.'s mines were situated, we decided, instead of going to a hotel, to utilize our camping outfit and pitched our tents on a small island in the Arkansas river. A tremendous rainfall somewhere upstream caused a rapid rise of the river, which overflowed the most of the island, put out our camp-fires, and even came up to the edge of the tents. We spent the latter half of the night in watching the flood and debating whether we should try to wade to the mainland or take to the trees if the flood should continue to rise and render our position untenable.

The roads leading out of Pueblo at that time were nothing but wheel-tracks; as these did not extend over half the distance to Mineral Point, we decided to pack the entire distance rather than change methods of transportation midway. Progress was slow, as the packers were Mexicans and knew more about *mañana*[1] than *prisa*.[2] Traveling through a new and beautiful country, however, had many compensations. Game was plentiful;



A PACK-TRAIN ON THE ROAD TO SILVERTON.

the streams had not then been whipped by thousands of fishermen, so by keeping a few miles in advance of the expedition during the day, I had glorious sport, the results of which greatly improved our bill of fare and lessened the drain on the supply of provisions which we were packing with us.

Late one afternoon, just as I was about to start back for camp, clouds of extraordinary density scudded over the horizon and darkness, accompanied by a terrific rain, came on so quickly that I was barely able to find my way to a little dirt-covered shack which I had passed not long

[1]Tomorrow. [2]Hurry.

before the storm came up. The cabin had been built by a home-seeker from Missouri who had a wife and two children. They had only one bed, very little to eat, and, even before we had disposed of a scanty meal of saleratus bread and bacon, the rain commenced to percolate down through the mud-covered roof and little murky streams were soon dripping down in every part of the cabin. I sat up all night on a cracker-box in a corner of the room with a *poncho* over my head trying to keep dry and get a few winks of sleep; but, after a most uncomfortable night, which seemed to last an age, morning dawned as clear and bright as if storms would be forever unknown.

I found my half-drowned horse and started back for camp. About the middle of the Wet Mountain valley I ran across a man who had been caught by the storm, spreading out his wet blankets on some rocks. Stopping to talk, I soon ascertained that he was a mining engineer for another mining company whose outfit was a few days behind ours on the same trail. This engineer was H. W. Reed. Leaving his blankets to dry, he rode back with me to our camp for breakfast, after which we hunted and fished together and had such a glorious time as only young, care-free, engineers in a new country could have.

One night we returned to camp and found everything in confusion. The packers, realizing that the expedition was in a wild country where there were no wagon-roads and no possibility of obtaining other packers, had struck. The president and secretary of the company were in a quandary what to do: whether to give in to the unreasonable demands of the packers or to wait there until new packers could be obtained from Pueblo. In an unguarded moment I suggested that, as the miners who were going in to the mines were doing nothing on the trip, there was no reason why they should not be trained to pack. This view was pronounced sound, but the question was, how were they going to be trained, as there was nobody who knew anything about packing except the strikers. After discussing the thing for some time, Reed and I came to the conclusion that we had seen the animals packed in the mornings often enough to be able to do it, so we had one of the quietest burros brought out from the herd and started in to see what could be done. A few attempts showed us that the mysteries of packing were not to be solved off-hand, but by sticking to it for nearly a day we finally learned how to throw the 'double-diamond hitch,' and then commenced to teach the miners, some of whom showed considerable aptitude, but the majority of them lacked both the knack and inclination. Still, they all saw the necessity for it, and after a day or two spent in practising packing and unpacking we were able to move, the foreman of the mine-crew taking charge while Reed and I rode along behind to give expert advice, which, in this case, was rarely successful unless accompanied by a complete physical demonstration. However, all things come to an end; after a laborious but uneventful journey we reached Mineral Point and began the development of the mines.

This alleged city had an altitude of 11,700 ft. and contained a motley assortment of tents, together with a few poorly-built log-cabins. The rain-fall was so great and flurries of snow so frequent that a tent was far from being comfortable as a residence, so Reed and I began looking for some one who could build us a cabin. We finally found a carpenter who said he could build the cabin if he had the logs. We were unable to find any one who could or would furnish the logs, hence Reed and I decided to do this ourselves. He had been brought up in the Maine woods and I on a Canadian farm, so we were both familiar with the use of an axe and soon had the requisite number of trees cut down and logs cut to the desired length. Then we were fortunate enough to find a packer who hauled them to the site with an old half-broken pack-mule. Once established in our new home we made ourselves as comfortable as possible, but, of course, were obliged to do our own cooking, and the same room had to be used for everything, including surveying instruments and my little assay-furnace, which was set up in one corner.

The development of the mines showed large bodies of ore, most of it extremely low-grade silver-lead. It was the company's intention to continue work on the mines throughout the winter, but an early snow-fall closed the pass at the head of the Lake Fork of the Gunnison before the winter supply of provisions arrived and we were all obliged to migrate.

There were no snow-shoes in camp and tramping through the deep snow over the range was the hardest trip I ever undertook. When we reached what is now the site of Lake City we found some changes, a few log-cabins had been built and one of them bore the sign 'Restaurant.' Reed and I, who had been cooking for ourselves all summer, immediately started to vary the monotony by ordering a meal at this alleged restaurant. The bill of fare consisted of very tough fresh beef and saleratus bread, after which they brought in some stewed dried apples, whereupon I remarked to Reed that I never expected to see dried apples served for dessert. He replied immediately with a great deal of emphasis: "Damn a country where dried apples are a luxury."

Conveyances of any kind were unobtainable, our animals were completely worn out, there was nothing to do but for us to finish the journey on foot; so we tramped up Slumgullion Pass, across the Cebolla, and down Spring gulch to the valley of the Rio Grande, which we followed down to the town of Del Norte, where we were fortunate enough to find a settler with a light wagon who agreed to drive us through San Luis Park, over Moscow Pass, down through the Wet Mountain valley, to Pueblo, where we took the train for Denver.

Coming direct from the populous East in the early summer, Denver had seemed to us a little, poorly built, country town, but, after four months in the wilds of the San Juan, when we came back to Denver it seemed to us an immense city and its somewhat primitive hotels the height of luxury.

Central City and Georgetown were at that time the oldest and most prosperous mining settlements in the State, so I decided to see something of the mines and

mills there before going East for the winter. At Georgetown, the last place visited was the Stewart mill, which, at that time, was the largest in the Rocky Mountains. The mill treated almost exclusively the high-grade silver ores of the district, the processes employed being the Von Patera and the Hunt & Douglas. Hyposulphite of soda was purchased in Germany, and, owing to the excessive freight-rates, it was extremely expensive; in addition to which, for various causes, the consumption was extraordinarily high. In the course of the visit it transpired that the proprietors were looking for a mining or metallurgical engineer who knew enough about chemistry to maintain the solutions in working order without excessive loss. The opening seemed too good a one for me to pass over, so I wired to Denver for my trunk and began the study of the interesting problem before me.

It was soon found easy to keep the solutions in working order, but the large loss of chemicals per ton of ore treated could not be reduced. The difficulty was finally solved by the manufacture of hyposulphite of calcium from the waste sulphur di-oxide from the roasting-furnaces. This furnished a supply of solvent so cheap that the question of loss became relatively unimportant and the cost of solution replacement was reduced to a small fraction of what it had been before.

The Hunt & Douglas portion of the plant, thanks to the careful instructions and constant advice of the two inventors, proved most successful, and, to me, one of the most gratifying results was the lasting friendship formed with both Thomas Sterry Hunt and James Douglas.

This work proved most interesting and occupied the winter of 1875-76, but when spring came, and with it reports of new discoveries in the various parts of the West, I became restive. Engineers were scarce, examinations and investigations were offered freely, therefore I naturally fell into the work of making examinations and investigations in widely separated localities, which gave, not only a widened experience, but an acquaintanceship with the operators and mines of the different districts that has ever since proved extremely useful.

In 1877 the discovery of lead carbonates in the hills bordering on the old alluvial diggings of California Gulch electrified the entire country and the magic word Leadville was on the lips of every one. Existing engagements kept me out of the new district until the spring of 1880, when I reached the camp in time to pack a gun and take a hand in the suppression of a strike. The privates were willing but undisciplined, and very few of the officers had any military training whatever. When the strike was ended I came out of the ordeal with a major's commission and a fixed determination that in the future I would do what I could to head off strikes rather than to participate in repressing them.

AFTER THE FIRST FALL OF SNOW; THE SAN JUAN RANGE.

Conditions in Leadville during its early days are so truthfully and graphically portrayed in Mary Hallock Foote's most interesting novels 'The Led Horse Claim' and 'John Bodewin's Testimony' that it would be a waste of time to describe them here, but one occurrence, with which I had some connection, deserves especial mention.

The Robert E. Lee, though not one of the earliest discoveries in Leadville, soon proved to be the richest mine in the district, and when it had reached a point where it was paying dividends of $90,000 per month its workings were completely flooded by an influx of water that for some time defied the efforts of the company to handle it. J. Y. Marshall, the president of the company, came to see me several times about it, but we could never come to

terms, principally, I suppose, because I had the boyish idea that the unwatering of a mine capable of paying that amount of dividends should contribute somewhat heavily to the financial assets of the engineer carrying on the work. One day, however, his patience becoming exhausted, he came down to see me and said, "Pump out that mine as quick as you can and when you get through send in your bill." Previous attempts at drainage had shown approximately the amount of water to be handled, which was entirely beyond the capacity of any stock pumps obtainable. I measured the compartments of the shaft carefully and then placed an order in the East for pumps as large as could possibly be passed through the openings. The pumps, after some delays, finally reached Leadville. At this time Mr. Marshall was a candidate for the office of district judge and, while he absolutely declined to take any part in the political campaign, he conceived the brilliant idea that, as the pumps would be ready to start a few days before the election, he could, without the loss of prospective judicial dignity, give a big reception when the unwatering of his mine began. The date for starting the pumps being set, my mechanics made several surreptitious trials of the machinery a day or two before to make sure that everything was right. Invitations to the 'blow-out' had been sent to everybody in the district from mine-managers down to nippers. The mine-office was filled with champagne and cigars for the managers and superintendents, while the shaft-buildings and ore-houses were loaded up with beer and 'smokes' for the miners. Promptly at 2 o'clock on the afternoon of the date set for the entertainment the steam was turned on, the mine-whistle began to blow, and the tooting was taken up by the whistles all over the hill. As the pumps started and water commenced to run down the mountain-side, the drinks began to flow down thirsty throats. The riotous scenes of the afternoon and evening were something to be long remembered. It is needless to say that Marshall was elected judge by an overwhelming majority, that the mine was soon pumped dry, and the long delayed dividends restored.

The fame of Leadville and the fabulous profits made by some of its mines brought into the city a continuous stream of 'tenderfeet.' While there was room for all of the miners that cared to come, the non-productive newcomers were far in excess of all possible requirements.

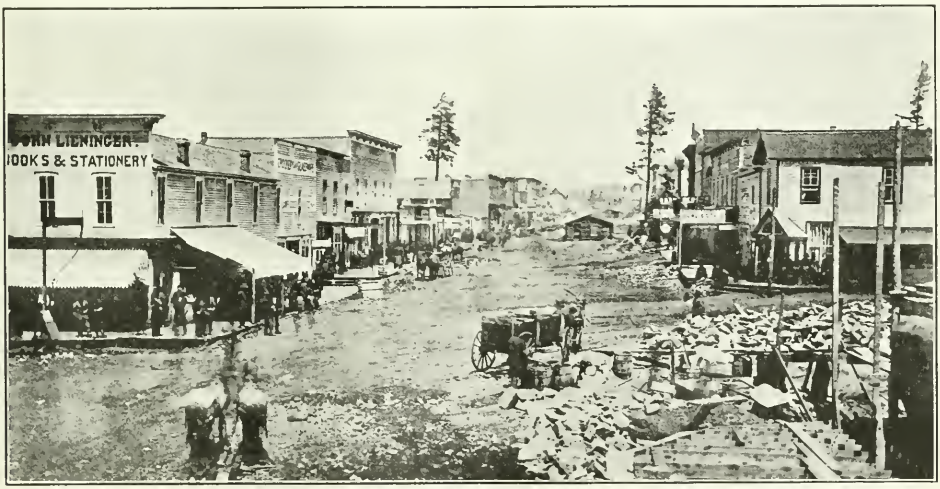
Among the young mining engineers who drifted into town about this time was one Ferdinand Van Zant, who, although he was equipped with a thorough technical education and a most pleasing personality, was unable to find engineering work of any kind. As his funds gradually dwindled, he gave up the hope of obtaining a position and began hunting for something farther and farther down the line until, ultimately, rather than allow his parents to know that he could not earn a living, he took a job as a waiter in a restaurant. One of the tables which Van Zant attended was principally used by the office employees of one of the big mines on the hill and before he had been at this work very long he one day overheard one of the men say that he wished he knew where to find "a bright intelligent young fellow who could make good figures and was accurate in his additions," for the position of weigh-master up at the mine. Van Zant immediately applied for the position and was accepted forthwith. A few months after this one of the foremen in the mine told the office-boys that he was certain there was an ore-shoot passing from the mine they were working into the adjoining claim and that if the boys would chip in together and get a lease on this claim he was certain they would make some money. The plan was carried out and Van Zant was one of the contributors to the pot. A shaft was sunk and a fine body of ore encountered. During the life of the lease the little company made a very handsome profit. At the expiration of the lease the owners of the mine refused to renew it, therefore, in accordance with the custom of the times, the lessees signalized the final division of the profits and winding up of the business by a champagne supper. At the close of the repast, when the cigars were passed, one of the party suggested that each should tell what he was going to do with his share of the profits. This was agreed to, whereupon one partner said he was going to buy a home for his mother, another that he was going to pay off the mortgage on his father's farm, the third was going to buy a herd of cattle, while still another was going to try and repeat his success by grub-staking some prospectors. Van Zant was the last to tell his plans and seemed reluctant to mention them, but on being pressed, he finally said, that he intended to go to London, rent a good suite of rooms, get a complete outfit of fashionable clothing, go into society, and marry the richest and most attractive girl he could get acquainted with. This program he carried out to the letter, marrying the daughter of Sir John Lubbock (afterward Lord Avebury). The happy couple took a wedding-tour through the United States, not forgetting to include in their itinerary the Golden West. Prospectors in those days had a habit of haunting the hotels with the hope of unloading their finds on unsuspecting tourists, and while at Butte one of these worthies drew Van Zant aside and showed him some ore from a new strike four miles from the town. Van Zant's engineering training and Leadville experience had made him a pretty good judge of minerals, he immediately recognized the value of the ore, and offered to go with the prospector to see his claim. The result was that Van Zant bought the mine and settled down to develop it.

This was the beginning of the famous Blue Bird mine, which, for many years, paid large monthly dividends with wonderful regularity.

After this had been going on for some years without a hitch, a small cloud appeared on the horizon in the shape of an apex side-line lawsuit with the Little Darling, a contiguous mine. This kind of litigation had been the curse of Colorado for some years, but this was its first outbreak in Montana. In order to obtain legal advice from experts in this type of litigation, Van Zant came to Denver and engaged the firm of Wolcott & Vaile to represent him in the coming fight. He also went to New York and secured the services of Dr. Rossiter W. Raymond, secretary of the American Institute of Mining

Engineers, as leading expert. The Little Darling owners, hearing of this, followed suit by engaging the firm of Patterson & Thomas as attorneys and myself as leading expert. The local attorney in Butte for the Little Darling mine was William Scallon, a young attorney who had just come over from the Coeur d'Alene on snow-shoes, pulling his law-books behind him on a toboggan.

The situation proved extremely complicated and one that was certainly never contemplated by the framers of the Apex Law, as, while there was a true-fissure vein in granite (aplite, to be more nearly accurate) the vein had been dislocated by a fault which gave it two parallel apices on adjoining claims, the Blue Bird and the Little Darling. By aid principally of the wonderful ability of the Little Darling company's local attorney, Mr. Scallon, secure professional advice arose from the fact that the mine-workings had already passed through the oxidized surface zone, carrying silicious gold and silver ore, down into solid sulphides carrying their principal values in copper. Daly was enterprising, far-sighted, and had abundant backing; while operating the mines he had already secured, he was continually on the look-out for other properties that might be expected to become producers or would protect him from future litigation. So rapidly did he push his various purchases and enterprises that I suggested to him one day that, owing to the irregularity of the orebodies and the difficulties of following them, we ought to have a competent geologist who would make a thorough study of the underground conditions, which was something I had not been able to find



HARRISON AVENUE, LEADVILLE, IN 1879.

the Blue Bird got the worst of it in the preliminary hearings, and, rather than allow the case to come to trial, the Blue Bird company bought the Little Darling from its owners at their own figures.

The principal owner in the Little Darling was Jim Murray, a noted plunger and a great friend of Marcus Daly. In his younger days Daly had been a working miner on the Comstock. When Butte was discovered he came there and secured the ownership of a number of the most prominent mines, which he organized into a company named after the principal mine in the group, The Anaconda Gold & Silver Mining & Milling Co., which name is still in gilt letters on one of the safes in the Anaconda Copper company's offices in Butte. Daly, through his friend Murray, probably during some of their all-night sessions at poker in the Silver Bow Club, managed to follow, with considerable interest, the Blue Bird-Darling litigation and when the final result was reached he decided to prepare for future contingencies by engaging Mr. Scallon as attorney and myself as consulting engineer to his mines. An additional inducement to time to do. His reply was simple, "Jist remember there are no strings on ye." As a result of this interview I began looking about for a desirable economic geologist and selected for this position Horace V. Winchell, under whose careful work and painstaking studies the mystery of the irregularities in the ore deposits was gradually unraveled. The geological department grew steadily in size and importance until it is now the most thoroughly organized and has the finest equipment of geological maps and sections of any group of mines in the world.

As the business expanded additional smelters were built, more mines purchased, and the entire hill hummed with ceaseless activity. Up to this time my jurisdiction was limited to the study of the orebodies and the passing of opinions on the desirability or undesirability of purchasing adjoining property. One day Mr. Daly said that the superintendents were all hounding him for more compressed air and that he had already bought more air-compressors than he had ever seen or heard of, and that he would like to know exactly how much more compressor-capacity was needed. He asked me to ascertain

this and report to him when he returned to Butte about a week later. A careful study of conditions showed that compressed air was being used for many things besides the operation of drills, such as running pumps, underground hoists, and ventilating. In addition to this, when the stopes on a level were worked out, the pipes, instead of being taken down, were allowed to remain in place and sometimes not even shut off from the main line. This was due, partly to the fact that the copper drippings dissolved away the iron to such an extent that it was rarely desirable to use old pipe unless it came from very dry workings. In addition to this the chain-gangs were exceedingly lax in tightening up leaks, a careful calculation having shown that if unnecessary waste could be prevented the mines already had more compressor-capacity than was needed. When I reported this to Daly he seemed incredulous. As the next day was 'Change Sunday' I asked him to come up to the Neversweat mine, where the principal compressors were situated, at 11 a.m. Of course, no drilling or underground hoisting was going on on 'Change Sunday,' and the superintendent and foremen were given orders to shut off all the pumps and ventilating pipes so that there would be no useful consumption of air. As the compressor-engines were fitted with indicators, it was easy to ascertain exactly the power necessary to maintain a constant pressure, or, in other words, to offset the leakage. When Daly came up to the mine and the engineers explained to him that it was taking 1100 hp. to keep up the leakage on the various pipe-lines his comments on the situation were amusing, strictly to the point, but hardly fit for publication. Next morning the chain-gangs were busy stopping leaks and the dealers in air-compressing machinery were a sadly disappointed lot.

This incident immediately enlarged my jurisdiction, one of the results of which was that we soon had a competent mechanical engineer installed, in charge of all the machinery on the mines, together with a sufficient staff to test thoroughly and bring up to the highest possible efficiency every boiler, hoist, and air-compressor on the job. Out of this work grew the necessity for a large central machine-shop where all kinds of repair-work could be carried out successfully at home. This change proved so satisfactory and economical that a central sample-grinding and assay-office was established, all of the small assay-offices at the individual mines being discontinued. This proved, if possible, even more satisfactory than the central machine-shop, for, with the power-driven grinding-machinery, it was possible to handle much larger samples and obtain more concordant results than when small samples from the drifts and stope-faces were crushed on the bucking-boards in the small assay-offices at the different mines.

Later, an unfortunate quarrel between Marcus Daly and W. A. Clark brought on a most bitterly contested mining lawsuit. The properties involved in this case were the Neversweat mine, belonging to the Anaconda group, and Clark's Colusa, two of the richest and most productive mines in the district. In this contest both Daly and Clark were intensely interested, as each considered his personal honor at stake; hence the contest was waged with greater earnestness than either of the men would ever have evinced for the mere money-value of the properties involved.

W. S. Keyes of San Francisco was given engineering charge of the case for Mr. Clark and I filled the same position for Mr. Daly, who on several occasions reiterated his old remark that there were "no strings on ye," meaning, of course, that expense was not to be considered and that the best engineering and legal talent obtainable should be engaged. This led to the engagement as attorneys for the suit, in addition to the exceedingly able legal force already in the employ of the Anaconda company, of Charles S. Thomas of Colorado and Joel F. Vaile, while, as experts I was fortunate enough to secure the services of Clarence King, N. S. Shaler, Rossiter W. Raymond, H. V. Winchell, W. A. Wiley, and E. E. Chase. We all put up at the old McDermott Hotel and were given a special table in the dining-room, where our meals, enlivened by the sparkling conversation and brilliant wit of the senior witnesses and attorneys, were a delight.

One day while puzzling over underground conditions and wandering through the workings alone, as I had done dozens of times before, I walked into some new workings on the extreme western end of the Neversweat orebody that had not yet had time to slack or cave. This showed what had been obscured in workings that were open for some time, namely, that the orebody, instead of tapering to a feather edge as orebodies usually do at their terminations, was cut off diagonally like the point of a chisel. A careful investigation showed a crack filled with finely-ground material crossing the workings diagonally. As the note-book I had with me was large enough to show both the Neversweat and Colusa workings on the same sheet, I drew with a blue pencil (from which it was afterwards named the Blue Fault) a diagonal line from the termination of the Colusa vein eastward to the western termination of the Neversweat. Of course, the next step was to go to the eastern termination of Clark's Colusa and see if anything like the same conditions could be observed there. A short investigation showed that the mysterious termination of Clark's Colusa vein to the east and the Neversweat vein to the west was probably caused by the same fault. This explanation was not immediately accepted by the other witnesses, but a critical examination of conditions in the different levels of both mines soon convinced all of them that the dislocation theory was correct. The faulting had evidently occurred before the termination of the mineralizing period, as the fault-fissure, in addition to the usual 'drag' ore, carried mineral as originally deposited. This proved the key to underground conditions at Butte, which, by the painstaking studies of the Anaconda company's geologists, has completely unraveled its mysteries and enabled them to map with certainty the position of dislocated veins.

Later, when Mr. Daly's health commenced to fail, the mines were sold to the newly organized Amalgamated Copper Company. Scallon and I were transferred with the property. H. H. Rogers, the virtual head of the Standard Oil Co., also assumed complete control of the

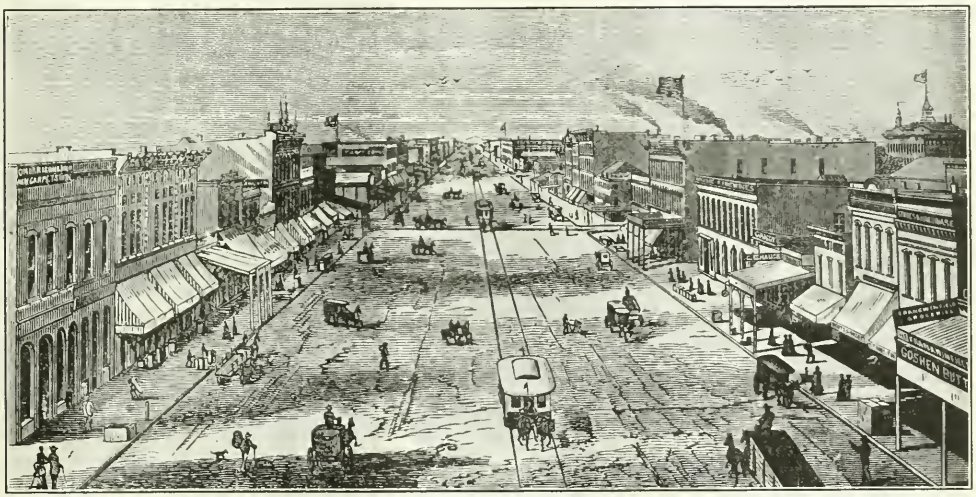
Amalgamated Copper Co., and insisted on extending my jurisdiction to include the smelters. I protested that I was not a metallurgist and that I was entirely incompetent for the work, to which he replied, "We know you are not a metallurgist, but you know more about the different metallurgists in the country than we do and all we expect you to do is to select the very best man you can find and do what you can to help him make a success of the new plant." I spent a few extremely anxious days and nights mentally weighing the experience and ability of the different metallurgists with whom I was acquainted or could gain authentic information about. After most careful consideration, I decided to offer the position to E. P. Mathewson, who was at that time in charge of the American Smelting & Refining Co.'s smelting operations in South America. The selection proved to be a most happy one for all concerned, as Mr. Mathewson's metallurgical skill, business ability, and unfailing tact have made the new smelting-plant at Anaconda not only a wonderful success, but the Mecca for copper metallurgists from all over the world.

As Mr. Rogers was heavily interested in iron mining and familiar with their economical methods of extraction, he naturally looked on copper mining costs as exceedingly high and was extremely anxious to know if some of the methods employed in iron mining could not be utilized in the extraction of copper ore. After talking the matter over, he insisted that I should visit the principal iron mines of Minnesota, where the Federal Steel Co.'s properties were situated, and familiarize myself with what they were doing. I had already seen a large number of the Minnesota iron mines but had never examined them with this specific purpose in view, therefore I was, of course, delighted at the opportunity afforded for studying their methods in greater detail.

As usual, I was provided with a private car, which was moved from one mine to another as the work progressed. The trip proved a most pleasant and interesting one, especially as I made the acquaintance of the different mine superintendents, from whom there was much to be learned.

Unfortunately, however, the mode of occurrence of the orebodies and the numerous surface improvements at Butte entirely prohibited the use of the more economical methods of iron mining, but observations on the trip fully established the desirability of back-filling stopes wherever possible. In consequence, the hoisting of waste from all our mines was discontinued and the material obtained from development was employed in back-filling.

As usual, however, Mr. Rogers' far-sighted views on the subject were entirely correct, and, while iron-mining methods are not applicable to Butte, they have since come into general use in many of the large copper mines in the United States, Chile, and Spain.



LARIMER STREET, DENVER, IN 1875.

Consulting-engineering on operations controlled by H. H. Rogers was a liberal education in itself, as his wonderful business ability and tremendous grasp of details enabled him to cover the field of possibilities so thoroughly that success in any undertaking was almost certain.

Owing to the time required to make the trip from New York to Butte, Mr. Rogers was rarely able to visit the mines, but his memory and power of visualization were so great that he had before him constantly a mental picture of what was going on in the West. Officials coming into his office from the mines and smelters were astonished to find him asking the most searching questions in the most familiar manner about everything that was going on, as if he had only visited the property a few days before. Again, the human side of the equation was constantly before him. Not only did he remember and make all his superintendents and managers feel that

he had a personal interest in them, but the health and welfare of his humblest employees were always given the most careful consideration.

How Mr. Rogers was able to carry the details of all the different lines of business in which he was engaged and keep intimate track of the widely scattered members of his staff was always a mystery to his friends, but may be partly explained by his ability to drop business entirely on leaving his office.

During the summer months he rarely remained in the city over-night, but went out to sea on his magnificent yacht, *The Kanawha*. With his wide circle of friends and lovable disposition, he generally managed to have with him some congenial company and an invitation to a trip on the yacht was something that none of his acquaintances ever declined. Among his special friends were Mark Twain and Tom Reed, who at that time was Speaker of the House of Representatives. These two intimates were usually invited together. Once when Reed had just been invited for a week-end trip on *The Kanawha*, he ran across Mark Twain and told him of the invitation before Mr. Rogers had time to invite him. Whereupon Mark Twain jumped to the conclusion that he might possibly be forgotten and sent the following letter:

"My dear Harry:

Have just seen Tom Reed and he tells me that he is invited to spend the week-end on *The Kanawha*, and I would like to remind you that a boat requires virtue as well as ballast.

Most sincerely,

S. L. Clemens."

As many a truth is told in jest, this letter was altogether too good to be lost, and Mr. Rogers immediately had it framed and hung up in his office, since, aside from the gentle thrust at Reed's ponderosity, the sentiment of the epistle was equally applicable to the conduct of human life and the management of corporations.

Venezuela has an area of 393,976 square miles, which exceeds that of Texas, Louisiana, and Arkansas combined. The population is 3,000,000, of which 73,000 is in Caracas, the capital. For twenty years a direct line of American steamers has run regularly between the United States and Venezuela, and this line has a mail contract with the post-office department, yet the steamers are said to be slower and inferior to those of the French and Royal Steam Packet lines between Venezuela and Europe. The monetary system is on a sound gold basis and no paper money is used as legal tender. All interest on the public debt has been paid promptly during the trying time of the War. For the fiscal year 1913-'14 the United States was the largest customer of Venezuela and also supplied a larger share of the imports than any other country.

The discovery of asbestos in Arizona has created interest; it is of good quality with a long fibre, being found near Globe and in the Grand Canyon. One of the largest blocks of claims was transferred recently.

Dredging in the Philippines

*Dredging was responsible for about 44% (₱1,030,000) of the total gold output of the Territory in 1914. Results of the Gumaos Placer Co., operating in the Paracale-Mambulao district are of interest. The company operated continuously throughout the year. Its dredge, built by the New York Engineering Co. has so far achieved an enviable record. On an original investment of ₱500,000, the company has paid in dividends during 27 months of operation the sum of ₱535,000, or 107%. The generally non-uniform character of the dredging ground in this district is exemplified in the record of the Gumaos dredge; the average value for different monthly runs varies from 6 centavos to ₱1.66. The average value for the whole period of operation has been 64 centavos per cubic metre. The cost of operation, according to the company's figures, is about 24 centavos per cubic metre dredged. The average fineness of the bullion is 873. The depth to bed-rock varies up to 17 metres, but has averaged about 11 metres. The gold recovered is fine and very sharp and angular. It is confined to a layer of wash usually less than two metres thick immediately over-lying bed-rock; the over-burden is largely clay. According to the general manager, Frank B. Ingersoll, the boat has yielded a total of ₱912,205 from 1,850,713 cu. yd. in 12,589 hours worked, an average of 49.29 centavos per yard. Of this, ₱380,678 was recovered from 875,303 cu. yd. in 1914.

The Paracale Bucket Dredging Proprietary, Ltd., and the Philippine Dredges, Ltd., closely associated Australian corporations, had four dredges at work during 1914. One of these started in November, and another lost a great deal of time as a result of litigation over title to the ground on which it was situated. In spite of obstacles, however, the year's record is good, and much credit is due William Telford, the general superintendent for the two companies.

The Malaguit Dredging Co. placed a new dredge on Malaguit river early in 1914. Some time has been lost in getting into proper running order, but the dredge has recovered a satisfactory amount of gold, and will undoubtedly do better later.

The Philippine Dredging Syndicate, and the Maximelo Dredging Co. each operated one dredge in 1914. About the middle of the year the former finally dismantled its old Risdon dredge, which was built in Masbate in 1905, moved over to the Paracale district in 1908, and has been digging on Malaguit river since that time.

The Mambulao Placer Co. is reported to have obtained exceptionally high gold-content from the tests of its dredging property at the head of Mambulao bay, and a New York Engineering Co.'s dredge will be erected at Mambulao during the coming year.

Several dividends were declared by the dredging companies during the past year, and the industry appears to be in a healthy condition, although more than 50% of the Philippine gold production is from quartz mining.

---

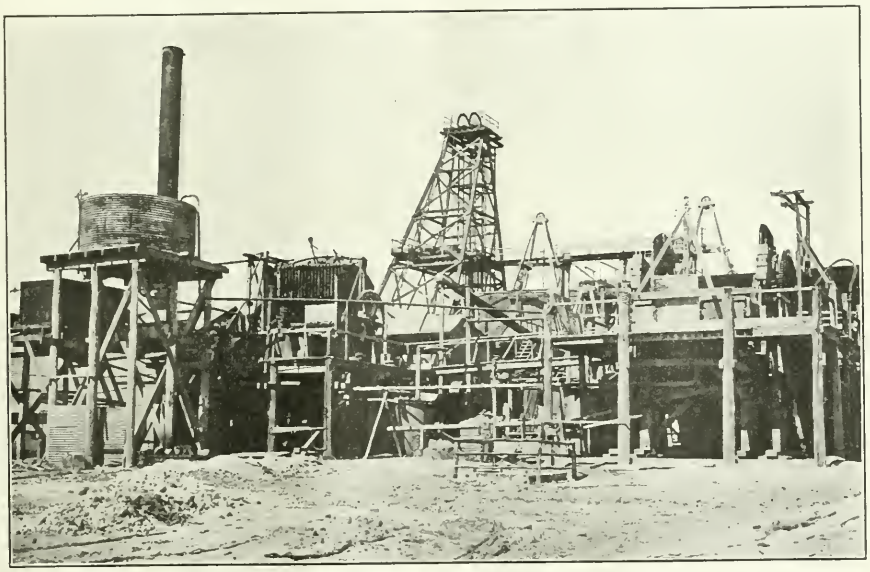
*Abstract from Division of Mines report for 1914.

Cyanidation in Western Australia

By V. F. STANLEY LOW

*The plant at the Corinthian North mine in the Yilgarn district may be taken as a fair exponent of such Western Australian practice in milling as entirely dispenses with amalgamation and employs only cyanidation for the extraction of gold from the ore.

The mine is excellently situated as regards transport, fuel, mine-timber, and water. It lies about 10 miles from Southern Cross in thickly timbered country, is served by pipe-line from the Eastern Goldfields Water-Supply, and is in direct railway communication with the capital and the seaboard.



THE CORINTHIAN NORTH MILL, SHOWING TWO RIDGWAY FILTERS.

The body of quartz that is now being extracted by open-cut methods outcrops at the surface with an average width of 20 feet. The dip is nearly vertical, inclining to the west; and the oxidized ore extends to a depth of about 90 ft. Only oxidized material is being mined and treated at the present time; but a further addition to the plant for the purpose of dealing with the sulphide ore found underneath the oxidized zone is now in course of construction. The sulphide is in the form of pyrrhotite; in order to render it amenable to profitable cyanidation the ore must first be submitted to a preliminary course of dry-crushing and roasting.

The ore from the open-cuts passes through chutes to the 100-ft. level and is trammed to the main shaft. The trucks are then raised to the brace, 48 ft. above the surface, and the ore discharged into a jaw-crusher placed immediately above the storage-bin.

The general outlay of the plant renders it eminently suitable for economical working; but the machine-shops and the main shaft have been placed too close to the open-cut and rather too near to one another, with the result that there is congestion of equipment around the shaft.

The power-plant consists of three Babcock boilers adapted for wood-fuel; these supply steam to the winding-engine, mill-engine, air-compressor, electric-light engine, and boiler-feed pumps. Approximately 186 long tons of firewood is consumed weekly in generating steam at a pressure of 150 lb. per square inch. Fouché atmospheric condensors are installed; but these may be regarded as water-savers rather than vacuum-producers. There is an adequate supply of salt water from the underground workings for all purposes other than the production of steam.

The treatment-plant consists of a jaw-crusher, ore-bin, 20 stamps, 2 tube-mills, 2 cone-classifiers, 2 centrifugal pumps (one as a stand-by), 2 thickeners, 4 agitators, 2 Ridgway filters, 2 double-ram pumps, a salt-water tank, battery-tank, solution-clarifier, 3 precipitation-boxes,

*Mining engineer, recently manager of the Corinthian North mine.

acid-vat, and the necessary furnaces for roasting and smelting the precipitated material. In addition to the above there were two grinding-pans, but, as I found upon experiment that these were serving no good purpose, they were soon eliminated.

The ore, after passing over the grizzly and through the 22 by 11-in. jaw-crusher, drops into a rectangular flat-bottomed storage-bin, 34 by 14 by 18½ ft., from which it is delivered by Challenge feeders to the 20-stamp battery.

The battery consists of four units of five stamps each, the whole being of the narrow-mortar Homestake type so often seen in Western Australia. Each stamp weighs 1250 lb., dropping 8 inches, 106 times per minute. The depth of discharge is set at 1½ in., and the order of drop is 1, 3, 5, 2, 4. The average duty is between 10 and 11 short tons per stamp per 24 hours. Screens of 17 and 16-gauge wire with 6 and 10 openings per linear inch are used, according to the nature of the ore to be crushed; but the screen of larger aperture is generally preferred. The mortars are fitted inside with liners of manganese-steel; and false bottoms are inserted from time to time below the dies in order to maintain the depth of discharge as the dies wear down.

Under normal conditions the material leaving the battery has approximately the following grading:

Mesh.	%
On 20	34
" 90	39
" 150	5
Through 150	22

Immediately upon entering the battery the ore comes into contact with cyanide solution, which is further strengthened by the addition of sodium cyanide as the pulp enters the agitation-vats later in the process. Lime is added to the ore as it enters the mortar.

The crushed material leaving the battery is conveyed by launder to a 4-in. centrifugal pump, which, working at a speed of 650 r.p.m., elevates it through a head of 27 ft. to two cone-separators, 6 ft. diam. and 7½ ft. deep.

The overflow from these cones, which is the material that eventually reaches the agitators and filters, has the following grading:

Mesh.	%
On 90	25
" 150	19
Through 150	56

It enters two circular thickeners constructed of 18-gauge corrugated galvanized iron, 25 ft. diam., the arms of which make one revolution in two minutes.

A screen-analysis of the underflow from the cones shows:

Mesh.	%
On 40	31
" 90	55
" 150	6
Through 150	8

This is delivered by launder to two tube-mills, 16 ft. long by 4 ft. 1 in. diam.; these make 31¼ r.p.m., each requiring about 40 hp. for their operation.

The liners of the tube-mills are of hard iron and are longitudinally corrugated. The discharge contains 55% of solids of the following grading:

Mesh.	%
On 40	13
" 90	60
" 150	10
Through 150	17

The discharge from the tube-mills unites with the material leaving the battery and the whole is delivered by centrifugal pump to the cone-separators, thus closing the circuit between the separators and the tube-mills.

Danish flints are used under normal conditions, but, in recent months, it has been necessary to resort to flints gathered in South Australia. These flints do the work of grinding satisfactorily, but their life is only about three-fifths that of the Danish, owing to their greater softness and liability to fracture.

The underflow from the 25-ft. thickeners is delivered to four agitators, each 18 ft. diam. and 8 ft. deep, the arms of which make 15 r.p.m. The agitators are constructed of ¼-in. steel plates and hold 57.8 tons of dry slime when the material contained has a specific gravity of 1.6. The stirring-arms are actuated by mitre-gearing through a vertical spindle 2½ in. square, which is free to move up or down through the horizontal members of the mitre-gear. The spindle and stirring-arms are suspended from an overhead frame-work by means of a chain that passes over a pulley and is attached to the upper and projecting end of the spindle by means of a swivel. After passing over the pulley the chain is led to a windlass, which stands on a platform placed on the steel tank of the agitator. By means of the chain and windlass the stirring-arms may be raised clear of such pulp as remains in the agitator-tanks when repairs to the agitator become necessary or when the plant is stopped for any considerable period. Each stirrer requires about 1½ hp. for its operation.

As the pulp enters the agitators an addition of sodium cyanide is made in quantity sufficient to leave the solution at 0.05% cyanide after agitation has been completed.

So long as care is taken to prevent the raw sulphide from mixing with the oxidized ore and entering the battery, the consumption of cyanide amounts to about ½ lb. per ton of ore treated. If, through carelessness or from any other reason, pyrrhotite is allowed to get into circulation in the plant, the consumption of both lime and cyanide is greatly increased. Under normal conditions about 120 lb. of lime is added to every ten tons of ore fed to the battery.

On the conclusion of agitation the pulp passes to a double-ram pump, which delivers it to two Ridgway filters. In these machines the filter-leaves are moved in a vertical plane through the arc of a circle from the pulp-bath to the wash-bath and reversely. Each filter contains 20 leaves, 5 ft. 6 in. by 4 ft. 2 in. over all; making due allowance for the frame-work, this gives a filtering area of 850 sq. ft. The whole mechanism, together with the pulp and wash baths, is raised to a sufficient height above the surface to allow of the delivery of the filtered

and washed pulp to a mixer 7 ft. high and 8 ft. diameter.

The pulp and wash baths are 11 ft. long, 6 ft. wide, and 5 ft. deep. Parallel with the length of the baths and mid-way between them, supported on substantial trestles, is the operating shaft, 8 in. diam. and 14 ft. 6 in. long. Worm-wheels 8 ft. diam. are keyed onto each end of the shaft, as are also radiating arms for carrying the filter-leaves and the heavy cast-iron weights used as a counter-balance against the leaves and their adherent pulp.

The leaves are attached to the arms through the agency of a hollow cast-iron girder or manifold from which 20 nipples $\frac{3}{4}$ in. diam. project. These nipples, which communicate with the hollow interior of the manifold, are placed in line along the bottom of the latter at intervals of 6 inches. Connection between the piping, which forms the frame of the leaves, and the nipples is made by means of short sleeves of rubber tubing; but the actual weight of the leaves is supported by steel rods bolted to angle-irons that project from the manifold at right angles to its length.

The manifold, where it meets the carrying arms, is circular in section and is held in bearings bolted to the arms. The leaves and manifold thus being free to rotate, the former hang vertically throughout the complete cycle of operations.

One end of the manifold projecting through the bearing is tapped to take a 3-in. gland by means of which pipe-connection is made with the vacuum-pump. Close to the gland the pipe carries an automatic valve, which is brought into operation at such time as it is necessary, during the course of filtration, to use or dispense with the vacuum.

By means of gland and piping, the opposite end of the manifold is connected with the compressed-air main. An automatic valve allows of the admission of com-

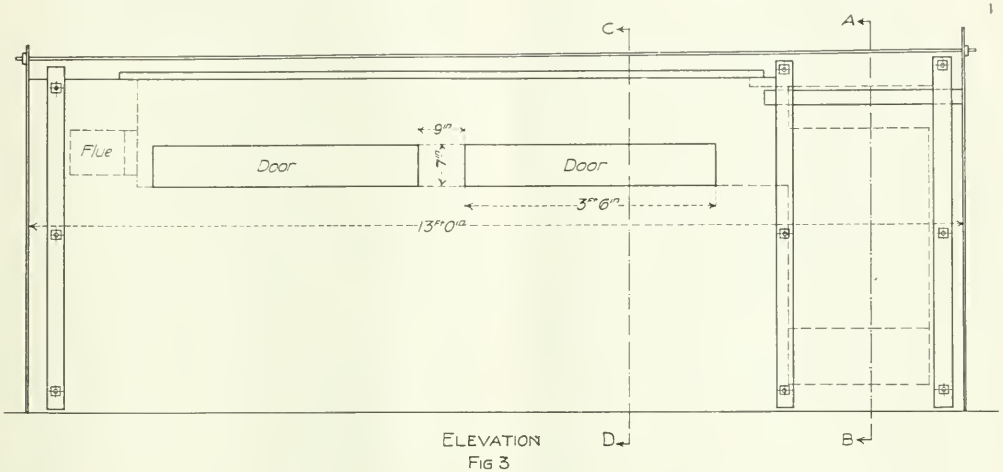


FIG 3

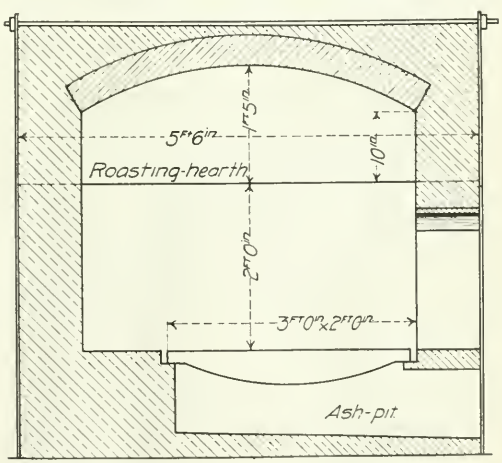
FIG 1.



SECTION AT A-B
FIG. 2

pressed air to the interior of the leaves at the conclusion of each cycle, when it becomes necessary to blow off the washed pulp, which then goes to the residue-mixer.

A 2½-in. shaft is placed behind the wash bath and parallel with the 8-in. shaft. At each end of the 2½-in. shaft is mitre-gearing that operates the worm-gearing attached to the 8-in. shaft. The 2½-in. shaft also carries two fast and two loose pulleys with the usual striking-gear, as well as a fixed pulley for the band-brake. The pulleys are operated from a counter-shaft, one by means of an open belt, the other by means of a crossed belt; thus, by using the striking-gear and throwing either one of the belts from the loose to the fast pulley, the arms carrying the manifold and filter-leaves may be moved backward or forward as desired.

In order to prevent settlement of the solids in the pulp and wash baths, two horizontal stirring-arms are kept revolving close to the bottom of each. These are attached to spindles that enter from below and are belt-driven through interlocking cogwheels which maintain a constant position of the arms relatively to each other. The shafts, where they enter the tanks, are fitted with the usual stuffing-glands to prevent the leakage of solution.

Immediately under the 8-in. shaft, and somewhat greater in width than the nest of filter-leaves, is a steel chute for carrying away the blown-off pulp to the residue-mixer. Water is admitted at the top of the chute which it helps to keep clean and, at the same time, it dilutes the residue to the extent required for subsequent pumping to the waste-dumps.

The cylindrical mixer into which the filtered pulp passes is 8 ft. diam. and 7 ft. deep. The 4-in. spindle that carries the stirring-arms is suspended from an overhead frame-work and revolves on ball-bearings at 30 r.p.m. It is belt-driven through mitre-gearing.

After leaving the mixer the residue, now of about 1.5 sp. gr., flows to a duplex-plunger pump, 12-in. stroke and 8-in. diam., by means of which it is delivered through a 4-in. main to the waste-dumps. The size of the delivery-pipe would appear to be somewhat small; but it has been found that pipes of greater diameter are liable to clog with solidified material if the velocity of discharge becomes too low.

A double-acting wet vacuum-pump is provided for producing the vacuum, the cylinders being of 8 in. diam., 10-in. stroke, 100 strokes per minute.

The following is the cycle of operations of the Ridgway filter: Starting at that part of the operations where the filter-leaves have been raised to a position vertically above the 8-in. shaft and the cake has been blown off, the attendant now operates the striking-gear and lowers the leaves toward the pulp-bath in which they finally become immersed. The automatic vacuum-valve opens as the leaves begin to enter the pulp and the vacuum gradually begins to rise from zero, eventually reaching 20 inches. During the progress of cake formation the valve on the pulp-main is opened and thus adds fresh supplies to the pulp-bath, an overflow being provided for carrying any surplus back to the pump.

The time of immersion varies from 10 to 20 minutes, according to the nature of the pulp. With some classes of ore the time for immersion might possibly be extended to 25 minutes with advantage. If the cake be of a gritty and porous nature, a cake 1½ in. thick may be formed in 15 minutes; but by far the greatest proportion of cake is formed during the first few minutes of immersion. Should the pulp have a greasy non-porous nature, such as is common to ores highly impregnated with mica, only a thin cake will be formed, no matter how long the time of immersion may be extended. With a non-porous pulp the attendant shortens the time of immersion. It is stated that the gradual rise of vacuum from zero to 20 inches is more satisfactory for cake formation than the sudden production of the maximum.

Under favorable circumstances a cake of about five tons of dry slime will have been formed on the filter-leaves, which are now raised by the attendant through the arc of a circle and lowered into the wash-bath. As has before been stated, the wash-bath lies parallel with the pulp-bath on the opposite side of the 8-in. shaft. Throughout this transit of the leaves, which occupies about 1¼ minutes, the vacuum is maintained; it is, of course, also maintained while the leaves are in the wash-bath. As soon as the leaves have entered the wash-bath a valve connected with the sump-solution tank is opened and the bath is kept full, any surplus being carried away by the overflow-pipe. The sump-solution tank draws its supplies from the liquor leaving the tail end of the precipitation-boxes. This liquor carries gold in solution to the value of about 5 pence, or 10 cents, per ton and also contains about 0.04% cyanide. The wash-solution, after having passed through the cake on the filter-leaves, is pumped to the battery-supply tank. There is no sensible enrichment of the wash-solution during the process of washing.

After washing has taken place for 10 or 15 minutes, according to circumstances, the attendant raises the leaves from the bath to the central position immediately above the 8-in. shaft, the vacuum is shut off, the compressed-air valve opened, and the cake blown off. As the cake drops to the inclined chute it meets the stream of water previously mentioned, which carries it to the residue-mixer and, at the same time, reduces its specific gravity to about 1.5.

This completes the cycle of operations as far as the Ridgway filter is concerned. The time taken for raising the leaves from the wash-bath, blowing off the cake, and lowering into the pulp-bath is about 2½ minutes, so that, allowing for periods of cake formation and washing of 15 minutes each and 1¼ minute for the transit from the pulp to the wash bath, the cycle of operations occupies 33¾ minutes. Taking the above time dealing with a porous pulp of 1.6 sp. gr., one Ridgway filter should deal easily with 200 short tons per 24 hours.

The 20 frames that carry the filter-cloths of the Ridgway filter are composed of black iron pipe, ¾ in. diam., bent into a rectangular shape to measure 5 ft. 6 in. by 4 ft. 2 in. The ends of the pipe are united at the centre of the upper side by means of a T-piece to which the

rubber sleeve connecting with the manifold is attached. The pipe-frame is strengthened by two flat bars of steel bolted from one side to the other at right angles to the longer axis. The inside of the pipe is perforated with ¼-in. holes at 6-in. centres. As a support for the filter-cloths, which are of 19-oz. duck, a piece of coir matting is tied to the inside of each frame so as to fill the interior area. The filter-cloths, which are machine-sewn in the form of oblong bags, are slipped over the frames and coir matting; the open ends are then sewn up. Lines of stitches, uniting the two sides of each cloth and passing through the matting are then put in by hand or machine in vertical lines at short intervals. The leaves are then ready for use. The filter-cloths are removed at intervals, as required, and placed in a bath of dilute hydrochloric acid for periods sufficiently long to dissolve the soluble incrustations that have formed on them. After being thoroughly washed in water, they are again ready for attachment to the frames.

The gold-bearing solution that is drawn through the filter during caking operations is delivered to an elevated tank from which it passes through clarifying-boxes filled with wood-wool to three precipitating-boxes of the usual rectangular form. Each box has eight compartments, 22 by 34 in., and 28 in. deep, the first of which is filled with wood-wool and the remainder with zinc-shaving. The boxes have a longitudinal inclination of 1 in 30, and the solution, leaving the boxes with a value of 5 pence, or 10 cents, per ton, goes to the sump, from which it is returned into circulation.

Attached to the smelting-room are the acid-tank for dissolving the zinc, the washing-box with attachment for obtaining a vacuum, a reverberatory roaster, and a crucible furnace. Until recently the roasting was carried out in a cast-iron muffle; but as this was found slow and uneconomical a reverberatory wood-fired furnace was substituted. This has given excellent results. The furnace was built with vertical walls tied across with steel rods in the usual manner. The space between the walls was then filled to the required height with sand upon which a brick floor was formed. On the brick floor transverse rails were laid to carry removable trays; and these rails extended into the smelting-room, so that the charging of raw slime and the removal of roasted material can now be carried out with ease and comfort. The roof of the reverberatory, with the exception of the fire-brick arch, is composed of worn-out tube-mill liners resting on transverse angle-irons, covered outside with asbestos fibre and then topped with sand. The furnace is fired from the outside, so there is no necessity for the attendant in charge of the firing to enter the clean-up room.

The roasted material is mixed with the necessary fluxes and smelted in plumbago crucibles. This is a slow process, and should be replaced by tilting-furnaces such as are in general use in other parts of Western Australia.

The following is the rate of wages paid in the mining and treatment departments, being, it is evident, not much different from wages in western United States:

	Per shift.		Per shift.
Mill-men	$3.60	Blacksmiths	$4.00
Filter-men	3.20	Laborers	2.52
Engine-drivers	3.36	Miners	3.44
Firemen	2.76	Trammers	2.64

Driving, cross-cutting, sinking, and raising are done on contract at prices varying in accordance with the nature of the work to be performed, such as hardness and broken condition of the ground, extent of the opening, and general difficulties anticipated. Machine-drilling in the open-cuts is contracted for at so much per foot drilled; but the spalling and rilling of ore to the chutes is done on wages, this being found more satisfactory.

Trucking from the chute to the station and from the brace to the cracker is contracted for at 20c. per ton; and, similarly, waste is delivered from the chute to the dump at a contract price of 24c. per ton.

The costs incurred in breaking, raising, and treating 5230 tons of crude ore and in carting and treating 418 tons of dump tailing during the month of January were:

5230 Tons of Crude Ore

	Per ton.
Ore-breaking and transport	$0.64
Removal of overburden	0.14
Treatment	1.27
Realization	0.05
Management and general expenses	0.25
	$2.35

418 Tons of Dump Tailing

Treatment	$1.268
Realization	0.052
Management and general expenses	0.252
	$1.572

Total working expenditure $12,974

In addition to the foregoing, the sum of $595 was expended in development work, being equal to 5.58d. or 11.16 cents per ton of ore raised. Management and general expenses includes the salary of the general manager. The following prices were paid for the under-mentioned stores delivered at the works:

Explosives, per pound	$ 0.19
Sodium cyanide, per pound	0.22
Zinc-shaving, per pound	0.14
Borax, per pound	0.12
Flints, per ton of 2240 lb	22.24
Fire-wood, per ton of 2240 lb	1.62
Lime, per cwt. of 112 lb	0.67
Battery shoes and dies, per cwt. of 112 lb	7.98
Wire-screen, per roll	36.00
Water, per 1000 gallons	2.40

From the statement given above it will be seen that the cost of production amounted to 2s.7.8d. or 63.62c. per ton of ore and the treatment 5s.3.43d. or $1.26 per ton, the final total cost amounting to 9s.9.73d. or $2.35 per ton of ore raised and treated; while the cost of loading and treating tailing that had accumulated during the earlier history of the company prior to the introduction of cyanidation amounted to 6s.6.65d. or $1.57 per ton of tailing. Costs of production and treatment are calculated on a basis of 2000 lb. per ton.

The Electrical Theory of Flotation

By THOMAS M. BAINS, Jr.

Introduction. If one turns to 'Elementary Lessons in Electricity and Magnetism,' by Silvanus Thompson and studies the fundamental principles of frictional electricity, as given in Chapter 1, a clearer idea of the causes of 'flotation' may be obtained. After seeing a few experiments, such as were performed at the Case School of Applied Science early in the year, it is not a difficult matter to believe that most of the phenomena are electrical in nature. For instance, if powdered galena ore, with a limestone gangue, be dropped into pure water, most of the powder will immediately sink to the bottom. As the air enclosed by the particles is expelled gradually, one sees the formation of 'armored' bubbles, some of which may last for days. Here is flotation without oil or acid. If nitric acid is added, the gas bubbles formed by the action of the acid on the gangue, will carry up particles of galena, some reaching the surface and bursting, while others too heavily loaded with galena particles will hover just below the surface. These will form clusters, resembling bunches of grapes, and when enough gas bubbles join the clusters, they start upward toward the surface, but generally before reaching there they are overloaded by particles falling from the bubbles that are bursting at the surface. The bubbles with their loads often resemble balloons, with the galena hanging on to the bottoms, as do the baskets of actual balloons. Some of the bubbles will be completely 'armored' while others will be nearly free from galena. Another experiment that may be successfully used in the laboratory for the flotation of the difficult sulphides, such as old rusty pyrite concentrate, like sweepings from floors of old mills, is as follows: Mix the ore with bleaching powder, some carbonate (say, sodium carbonate), and water. Put the mixture into a glass beaker and add concentrated nitric until red nitrous fumes are given off. Chlorine also will be evolved. The bubbles of gas are so highly charged electrically that pyrite from the Mother Lode between 10 and 20-mesh size was floated, making a complete separation from the quartz gangue. In this experiment the nitrous oxide was the active agent, for if the same experiment is conducted with sulphuric acid, no such separation takes place. Assayers are familiar with a similar phenomenon when treating blister copper with concentrated nitric acid and heating. Nitrous oxides are formed and the metallic copper is floated, a froth of copper being the result. Carbon dioxide does not seem to be as active as the nitrous oxides or chlorine bubbles.

Electrification of the Bubble. Two different substances, whether gaseous, liquid, or solid, when brought intimately into contact and moved one over the other, always produce electrification. Difference of temperature of two similar substances in frictional contact will cause electrification, the warmer usually being negatively charged. Something certainly happens when the surfaces of two different substances are brought into intimate contact, for the result is that when they are drawn apart, they are oppositely charged. The nature of the charge depends on the substances. Fur rubbed on glass electrifies the glass negatively; while if glass is rubbed with celluloid it will become charged positively.

A blow struck by one substance on another produces opposite electrical states on the two surfaces. Again, the evaporation of liquids is accompanied by electrification, liquid and vapor assuming opposite charges, though this is only apparent when the surface is in agitation. A few drops of copper sulphate thrown on a hot platinum plate produces violent electrification, as the copper sulphate evaporates. Electrical charges are set up by various other means, such as vibration, disruption of material, crystallization, combustion, pressure, and chemical reactions.

It would seem easier therefore to electrify a bubble than to keep it from being electrified. I assume that the bubbles are electrified, whether by means of air being forced through canvas, by beating air into water with blades, or by other means. The next step is to consider the properties of an electrified sphere. These may be illustrated by suspending two light spheres of conducting materials near each other by means of silk threads. Upon charging the spheres with like electric charges, they will repel each other, but if a conductor is brought toward them, both are attracted to the conductor. Of course, if the spheres touch the conductor and the conductor is grounded, then the spheres lose their charges. If the conductor is insulated from the ground, then upon contact with the spheres, the conductor receives a similar charge and the spheres will be repelled. Suppose that the spheres or conductor are covered with an insulating film. Then the spheres and conductor would remain as close together as the films would permit. So air bubbles that are electrified will attract conductors near them that are free to move. Air, being a poor conductor of electricity, the bubbles as a whole do not discharge immediately upon contact with a conductor. The only part of the surface discharged is that in immediate contact with the conductor, and this discharged film of air acts as a dielectric and non-conductor to the rest of the bubble, which remains charged for some time.

The amount of electrification of the bubble will depend on various conditions, such, for example, as the amount of friction produced by the blades of a Minerals Separation machine. Increase the speed and the electrification is greater and the attraction for conductors will increase, reducing the proportion of conductors in the tailing. Referring to the *Mining and Engineering World* of Janu-

ary 17, 1914, page 99, the speed of agitation and the percentage of extraction is given as follows:

Speed of blades, r.p.m.	Extraction. %	Weight of product. Gm.
1800	68	39
1200	54	32
900	46	26
600	39	18

The extraction seems to vary directly as the square root of the increase in speed. But it will be observed that with the increased extraction, the percentage of sulphide in the concentrate decreases, due to the attraction of the small particles of mixed gangue and sulphide. If the bubbles are highly charged, the concentrate will not be as clean in a particular case, as if they were less charged.

Vapors and gases may be highly electrified. The Armstrong hydro-electric machine, devised by Lord Armstrong, gave sparks of 5 to 6 feet. The friction of a jet of steam through a wooden nozzle generates the charge on the particles of condensed water in the steam. Gases derived from chemical reactions are also often highly charged, such as the nitrous oxides in the above experiments.

Relative Conductivity. From the above, it appears that to float a mineral, it must be a conductor. The following table of relative conductivities is taken from Landolt-Bornstein 'Physikalisch-Chemische Tabellen,' 1912, fourth edition:

Silver	681,000	Pyrite	41.7
Copper	634,000	Magnetite	1.24
Gold	455,000	Chalcopyrite	0.983
Iron	113,000	Manganese di-oxide	0.16
Covellite	8,000	Cuprite	0.025
Galena	3,350	Siderite	0.00014
Graphite	700	Quartz	0.844×10^{-14}
Pyrrhotite	119	Diamond	0.211×10^{-14}
Chalcocite	91		

From this table, it would seem that the metals and sulphides that may be recovered by the flotation method are all conductors. The chalcopyrite figure seems low, but the flotation properties of sulphide minerals vary, and the variation in the conductivity of the different minerals may have something to do with this. The better the conductivity of the valuable mineral, the easier is it floated, other factors remaining the same.

The Insulating Film. The next important question in the problem is the action of the oils, resins, or other agents now used in flotation. Working from the electrical standpoint, it is necessary to prevent the charge of the bubble from being dissipated and thus breaking down the froth, before it is desired. Oils and other substances have a tendency to coat the metals and minerals that are recovered by flotation, and if the air bubble is completely surrounded by these particles, an envelope of oil or other dielectric will insulate the bubble and prevent the dissipation of the charge. Without a dielectric film about the bubble no permanent froth would be formed. It is, therefore, necessary to add some material of great dielectric strength that has the tendency to coat the valuable mineral.

The words 'dielectrics' and 'non-conductors' or 'insulators' should not be confused. A 'dielectric' is a substance that is not only a non-conductor, but is also one that takes part in the propagation of the electric inductive forces. All dielectrics are 'insulators,' but equally good insulators are not necessarily equally good dielectrics. Air and glass are far better insulators than ebonite or paraffine, but the inductive influence acts more strongly across a slab of glass than across a slab of ebonite or paraffine of equal thickness, and better still across these than across a layer of air of the same thickness.

It may, therefore, be possible to use a frothing agent, as is well known, that is not an oil at all. I have done this and formed froth that has lasted for weeks. For instance, if in the experiment mentioned in the first part of this article, with galena ore, a little alcohol is first mixed with the galena, before the water and acid is added, then a heavy mass of bubbles and galena particles will be formed, too heavy to rise to the surface.

As the influence of the charge acts inversely as the thickness of the film, it is imperative that some dielectric be used that will create a very thin film about the valuable mineral. The dielectric must also be of such a character as to aid the formation of a great quantity of small bubbles in the liquid. It is difficult to create and maintain small bubbles in pure water. It is here that surface tension phenomena probably play a part in flotation.

Acidity of the Pulp. In D. G. Campbell's article in the *Mining and Engineering World* of January 17, 1914, he gives the following results of acid variations:

Acid, Gm.	Extraction, %	Weight of product. Gm.
0.0	63	67
0.2	50	60
0.4	51	35
0.4	48	30
0.8	40	26

Other tests also show that the extraction decreases as the acidity increases, but the amount of gangue in the concentrate decreases much more rapidly. With an acidified pulp, a cleaner concentrate is obtained. Also better results are obtained if the acid is added before the oil to the agitation-tank.

As to the action of acids and alkaline substances in the pulp, little seems to be known, but according to the electrical theory, the addition of these substances causes the conductivity of the pulp to increase greatly. It is a possibility that if the acid is not added before the oil, that the gangue, oil, and conductors are all electrically charged by reason of the friction. The conductors would be positively charged, while the other substances and the air bubbles would be negatively charged. If the pulp is a poor conductor, as it would be if water is not acidified or otherwise made a conductor (pure water being a very poor conductor), the charges on the gangue materials would remain for some time and the conductor (sulphides, etc.) would attract the gangue as well as the bubbles and oil, thus causing gangue to be taken up with

the bubbles. By the addition of acid, the charges on the surface of the solids are discharged to the ground, and the bubbles and the oil, which will not be instantly discharged as are the solids, will attract the conductors.

Conclusions. It might be stated here that the electrical theory was taught last year, as possibly explaining flotation phenomena, to the class in ore-dressing, at the Case School of Applied Science.

The above mentioned method of floating conductors may be used for the rapid determination of certain ingredients in ores that are amenable to the flotation process. It requires only a beaker and a few chemicals, no flotation machines being needed. For the rapid approximate determination of insoluble in a smelting ore, the method will give a fair result within a few minutes. If the conductor is readily acted upon by nitric acid, the results may not be satisfactory, but by addition of oleic acid the dissolving action of the acid is reduced.

The following summary of the requirements for 'flotation,' considered from the electrical standpoint, may be of practical use:

1. Ores containing valuable minerals or metals that are good conductors are the only ones that are suitable for flotation.

2. To buoy these conductors, it is necessary to supply enough electrified bubbles from below to float particles of the conductors that are attracted; hence the smaller the bubble, the better the result, the amount of gas being the same.

3. Some dielectric fluid is necessary to cover the conductor or the bubble, to prevent the dissipation of the electric charge. The thinner the film of dielectric and the greater its dielectric strength, the greater the effective attractive force and the more permanent will be the froth.

4. Some material must be added to the water to increase its conductivity, to obtain a clean concentrate; acids in small quantity are now used.

Pulmonary Disease Among Joplin, Missouri, Miners

*The conditions of working in the zinc-lead mines of the Joplin district have been thoroughly studied by A. J. Lanza and Edwin Higgins, who make the following conclusions and recommendations:

Conclusions. 1. The death rate from pulmonary diseases is unusally high among the miners of the Joplin district.

2. Poor housing, exposure, alcoholism, the use of common drinking receptacles, and overwork all tend to spread infection and lessen the power of the miner to resist disease, but the prime factor in causing pulmonary trouble is the rock-dust in the mines.

3. Rock-dust in the sheet-ground mines, although not made in great quantity, as compared to mines with more restricted working places, is harmful to the miner for two reasons: (*a*) because he is exposed to it practically during his entire shift, and (*b*) because the dust is made up chiefly of particles of insoluble flinty chert with splintered and knife-like edges.

4. This rock-dust is produced by the blowing of dry holes, squibbing, boulder-popping, drilling without water, shoveling, tramming, roof and pillar trimming, and the dumping of the bucket at the surface.

5. Certain precautions will abate the rock-dust.

Recommendations. 1. The following means should be employed for the abatement of rock dust in the mines:

(*a*) Provide a water-supply for every working face by the laying of a separate water-line.

(*b*) Where drills are operated without water, attach to the hose leading to the face a 5 or 6-ft. length of pipe with a nozzle from ½ to ¼-in. diameter. Make and enforce such regulations as will ensure the use of this water-spray for the purpose of wetting drill-holes, the face, and the broken rock about the face. For the purpose of washing drill-cuttings from drill-holes, this hose may be attached to the long pipes now in use for blowing out drill-holes.

(*c*) Where there is in use some type of drilling-machine that provides for water passing through the core of the drill-steel into the drill-holes, make and enforce regulations that will ensure the spraying of the face and broken rock for short periods at such times as the drill may not be in operation. For this purpose the water-hose must be uncoupled from the drilling-machine, unless separate water-connection is provided.

(*d*) Make and strictly enforce rules against squibbing and boulder-popping while the shift is underground, and against the blowing of dry holes at all times.

(*e*) Improve ventilation by the opening of new shafts whenever practicable.

2. Do away with common drinking-cups and kegs, and water-pipes which allow the miner to bring his lips in contact with the orifice. Substitute the well-known sanitary drinking fountain when practicable, or have miners bring their own water-supply in individual containers.

3. Do not employ as shovelers men under 20 years of age.

4. Through co-operation among the operators, provide a maximum daily tonnage for shovelers, so that they can not injure their health through overwork.

5. Provide a warm, dry, and clean place in which the miners may change their clothes.

6. Through intensive educational campaigns in the public schools, and among the miners themselves, disseminate information as to the harmful effects of insanitary practices and conditions, such as crowded living quarters, overwork, exposure, dissipation, the breathing of air polluted by powder-fumes and rock-dust, and the use of common drinking devices.

*Abstract from *Technical Paper* 105, of U. S. Bureau of Mines.

Plain Writing

By GEORGE OTIS SMITH

*Two years ago I spoke to the American Mining Congress on the subject 'Plain Talk'—both preaching the use of direct statement and trying to practice what I preached. Of late, my thoughts have turned more and more to the need of the use of popular language in stating technical results; hence this afternoon I venture to discuss plain writing from the standpoint of a Government scientist. For twenty odd years my association with scientists has been fairly intimate and though I may not qualify in plain writing myself, I can claim large acquaintance with both the written and the printed page whose meaning is far from plain.

At its best, science is simple; for science is not much more than arranging facts so as to set forth the truth. Scientific thought is exact and direct; and scientific writing must therefore be accurate and to the point. The scientist should think directly and with the precision of one of the instruments of his trade, and above all his language must present that thought exactly.

In scientific writing, this need of exact statement has led to the use of special terms, words that keep their razor-edge because used only for hair-splitting distinctions. In a certain degree this adoption of words not commonly used is unavoidable and therefore defensible. Yet, in many instances the practice is carried to an extreme and far too often the result is a highly specialized language so distantly related to our mother tongue, that as a preliminary qualification the writer has to pass a civil-service examination and the reader usually finds himself 'shut out' and facing a 'No Admittance' sign unless he happens to possess the degree of Doctor of Philosophy.

Mind you, it would be folly to throw away these tools so well fitted for special purposes, yet it is no more the part of wisdom to put them to every-day uses. The task for the scientist is to decide when to use his technical terms and when to talk United States. Of course, any writer's first duty is to be intelligible. Choice of language thus resolves itself largely into an understanding of the audience. If a scientific investigator desires to announce his discovery to his fellow-workers, he does well to use those exact terms that carry the same shade of meaning the world over and indeed may have the same form in several languages; if on the other hand, his results have immediate value for the mine-operator or the prospector, the geologist does not and cannot accomplish his purpose unless he writes in plain language, using words possibly less exact but surely more understandable.

It may be, I have stated the case too simply, so that this matter of plain writing may seem altogether easy, yet making out the prescription is always much easier than effecting the cure. Indeed, I suspect the difficulty is largely an internal trouble with the author, so deep-seated that my simple prescription of fitting the language to the reader does not reach it.

Sir Clifford Allbutt in his 'Notes on the Composition of Scientific Papers' lays down the plain rule: "Take pains therefore, with yourself first, then with your reader." His idea that clear thinking must be the first step to plain writing, of course deserves our endorsement, based upon experience. How common is the sad discovery that a piece of obscure writing is simply the product of roundabout reasoning or twisted thinking. Printer's ink unfortunately possesses no magic properties as an agent for clarifying muddy thoughts. Yet, no doubt it sometimes happens that some of us try to cover up with long words our uncertainty in thinking. So in preaching reform in scientific publications, those of us who are doing the work must realize that plain thinking comes first. There's the rub!

It is therefore not a coincidence that some of the deepest thinkers in geological science have also possessed a literary style conspicuous for clarity of expression. On the other hand, some authors whose English needs the most editing are equally careless in their quotation of facts determined by others, and indeed in the statement of their own observations. I mention this simply to show that I am strong in my belief that plain writing is not something beneath the plane of endeavor of the scientific investigator—indeed, it is something to attain which the most of us need to aim high—to raise our standards of scientific thinking. The use of common words is worthy of any writer, if his purpose is to transmit thought.

The discussion of plain writing at this time is not academic, because my real purpose is to take this opportunity to announce to you the policy of the United States Geological Survey on this subject. Our explorations, surveys, and investigations are in the public interest only as results are made public. This policy is as old as the Geological Survey itself, but several things have given a special impetus to the development of this policy. Beginning in August a year ago, a large volume of inquiries from producer and consumer of minerals came pouring into our office and as never before the Geological Survey became a kind of 'Central' to the mineral industry. This opportunity for a larger service to the public not only resulted in gratifying relations with a large number of correspondents, but the rendering of such service has proved instructive to the public servants charged with the duty. Many of us on the Survey staff have acquired a keener realization of the need not only of giving the public the facts, but also of making those facts intelligible and useful to the citizen who may lack professional training in geology or engineering.

Another line of larger service has been the issue of four guide-books to this great Western country, in which the purpose has been to inform the traveler concerning the resources of this part of our country as well as to unfold to him in attractive form its fascinating geology. The effort to meet the public need of authoritative information of this type seemingly has met with success,

*An address delivered before the American Mining Congress, at San Francisco, September 22, 1915.

and other guide-books in this series will follow in other years. More than that, however, the influence of this innovation is already felt, and the evident appreciation by the general public of this type of popular description is encouraging the Survey writers. The educational responsibility of this Federal service is being more fully realized and we intend to give much more attention, both to the simplification of the language of the professional publications and to the issue of reports that are popularly descriptive and instructive without loss of exactness. Even if plain language is used, our reports should be no less efficient vehicles for professional discussion or for announcement of geologic discoveries.

For thirty-six years the United States Geological Survey has reached an ever-widening circle of readers, and even in those first years of the Survey's life, King and Emmons and Gilbert gave to the West the results of their work in strong and forceful English. Yet, with the growth of the organization and the development of the science, the tendency toward highly specialized writing has been too marked and the present plea for plain writing has become necessary. The Government scientist has at least two obligations: first, that of making his investigations more and more exact in method and direct in result; second, that of making his product, the written report, such as to meet the needs of not only his professional associates but also the general public.

It is our ambition that the reports of the United States Geological Survey shall be written in the language of the people.

Precipitating Action of Carbon in Cyanide Solutions

By W. B. BLYTH*

†Graphite under suitable conditions will act like oil in the flotation process, and will selectively float certain finely-divided mineral particles. This factor must be taken into consideration when assaying the graphitic scum which appears on the surface of the pulp, or else an erroneous impression is likely to be formed as to the causes which tend to make this scum assay so high in gold.

In at least two cases known to me this factor satisfactorily explained the high assay-value of the scum, and showed that it was not due to premature precipitation caused by the graphite. In one case in roasting 'scum' from a Kalgoorlie plant, some sulphur was observed to be coming off. An analysis was made, and it was found that the sample contained both iron pyrite and tellurium. As all the gold in this ore was associated with the pyrite and tellurium, the presence of both in the scum was sufficient to account for its value. On another occasion, while investigating the treatment of an ore that contained both graphite and mispickel, and in which all the gold was associated with a small proportion of mispickel, the graphitic scum was found to be largely comprised of this mineral.

Unfortunately, the records of experiments made at the time are not now available, so exact data cannot be given.

Last year I was engaged in elaborating a scheme for the treatment of an ore containing much graphite and mispickel. Concentration tests showed that a large proportion of the quartz could be reduced to such a low value that it could be discarded direct; also, that the mineral in the slime could be readily floated off, and that this mineral (owing to the graphite) would float just as well without as with the addition of oil as a floating medium. Unfortunately, the froth in both cases was too bulky for the process to become commercially applicable.

Mr. Feldtmann's experiments are quite conclusive as regards the precipitating action of graphite (or the precipitating agents) contained in the West African schist, but in view of all the conflicting evidence that has been brought forward and published in the technical press during the last decade, we seem to be as much in the dark as ever as to why graphite *per se* precipitates gold. In some cases the result is due to contained occluded hydro-carbons, or some other carbonaceous matter associated with the graphite, while in other cases these factors are absent and the cause of the phenomena is not apparent. Unlike E. S. King, I have never been able to prove that West Australian samples of this variable member of the carbon family do precipitate gold.

Experiments have been carried out on Kalgoorlie Laverton, Murchison, and Southern Cross ores with negative results; in fact, in some cases when the samples contained a little gold, the pregnant auriferous solution was found to have increased in value during eight hours' agitation. From the mass of evidence brought forward it seems proved that pure clean massive graphite will not precipitate gold. As instancing this point there is one mine at Kalgoorlie where all the old plumbago melting-pots are regularly ground in a ball-mill and amalgamated, agitated with cyanide solution, mixed with the current slime, and filter-pressed. The metallurgist in charge of this plant assured me that a good extraction was obtained and no harmful effects were noted.

The effectiveness of graphite as a flotation medium is largely dissipated upon roasting, but if the roast is bad it will still be capable of acting in this manner.

The reason why the gold cannot be dissolved out of this selectively-floated mineral, is probably that the greasy graphitic scum effectively insulates the gold particles from the action of the cyanide solution.

*Formerly with Bewick, Moreing & Co., Kalgoorlie, Western Australia.

†Excerpt from Bulletin 132, Inst. M. & M. Discussion on original paper by W. R. Feldtmann.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

FRICTION OF WATER in pipes increases as the square of the velocity of the water.

FROM EXPERIENCE with tread-mills in British prisons, it has been learned that it would require the work of 40 men of 150 lb. each to develop one continuous horse-power.

MINERAL EXPORTS of Peru include the production of Bolivia, the adjacent republic, so that the figures given on page 622 of the PRESS of October 23, for Peru, will be properly understood.

METALLIC MAGNESIUM, it is claimed by scientists, can be substituted for aluminum, and for serving as electrical conductor an alloy of magnesium and aluminum is said to be commercially practicable.

MINE TIMBER should have the bark stripped off before being shaped and put in place. By hand a man can peel up to 60 logs per day, but by using a pneumatic hammer with suitable chisel up to 200 per day can be done. When the bark is removed rotting can be detected.

TAKING the population of the world at 1,732,000,000, the average use of copper per capita per year is 1.3 lb. Europe is using an average of 3.1 lb. per capita per year, North America 6.2 lb., United States 7.7 lb., while Africa, Australia and Asia combined use only about 0.008 lb. per capita per year.

AIR-BLASTS are generally associated with underground work, but an accident to the aerial tram at the Tomboy mine, Telluride, Colorado, early this year, was attributed to a snow-slide that came down the mountain on the side of the canyon opposite the tramway, and, mainly by force of the accompanying air-blast, destroyed and carried away two cable-towers.

THE COST of producing an ounce of gold at well-known gold mines is given as follows: Alaska Treadwell $11.85, North Star $11.08, Yuba dredge $6.26, Camp Bird $7.65, Portland $15.94, Homestake $13.72, Goldfield Consolidated $11.93, East Rand Proprietary $13.41, Mysore $8.39, Sons of Gwalia $14.84, Waihi $12.20, Yukon Gold (Dawson dredging) $9.76. The figures do not include any amortization nor interest on principal, and are not all for the same financial year.

NAMES of many minerals have the termination 'ite,' and a correspondent wishes to know its meaning. According to Dana the ending 'ite' or 'itis' (the original of 'ite') was used, according to system, among the Greeks, and adopted from them by the Romans, for the names of stones, it being one of the regular Greek suffixes. It was added (as 'ite' at the present day) to the word signifying quality, constituent, use, or locality of the stone. In 1783 Werner introduced personal names into mineralogy; these also have the suffix 'ite.'

BALL-BEARINGS are now made of chrome steel, as are some roller-bearings. This steel contains 1.3 to 1.6% chromium, besides small amounts of carbon, manganese, and silicon; phosphorus and sulphur being detrimental should be less than 0.02%. The balls or rollers should be absolutely uniform in size. In ball-bearings a slight difference in the size will cause the larger balls to take more than their share of the load, tending to deformation, while the smaller balls will be compelled to slide, resulting in breaking or flaking of the balls and raceways.

CONSTRUCTION of mine plants is fruitful of many accidents. This is due, primarily, according to the Anaconda company's publication *The Anode*, to the fact that the conditions under which the work is done are constantly changing, and that it is generally impracticable to make the working places as safe as they would be made under more stable conditions. Another matter that has a great effect upon the number of accidents that happen is the fact that most construction work is a rush job. Foremen and men get out to break records and are keyed up to work at the highest rate of speed, so that the taking of a chance that might cause an accident becomes a matter of comparatively slight importance to them. Among the most important causes of such accidents are: improperly built scaffolding, holes in floors that allow men falling through, loose material falling on men below, hoists not properly guarded, careless handling of electric wires that may interfere with construction, bad slings and tackle, and heavy materials slipping from tackle.

LOCATION of a mining claim is not valid unless based on a mineral discovery within the lines and on the actual ground of the claim, although it is known that a large number of locations are made without mineral discovery. It has been held by the Land Department at Washington and by many courts, that "a valid location of a mining claim may be made whenever the prospector has discovered any indications of mineral, so that he is willing to spend his time and money following it with the expectation of finding ore." Applicants for mining patent have their ground examined by a Federal Government mineral examiner. The position of a locator attempting to hold a location without a mineral discovery cannot be fully defined. The locator is entitled to be protected in his occupation of the ground, especially while trying in good faith to make a mineral discovery. Under the law, other locators are also entitled to go upon the ground, so long as it can be done peaceably and without interfering with the first claimant, and under such conditions to attempt to make a discovery. In the case of these rival claimants, the claim goes to the one making a discovery first.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ATOLIA, CALIFORNIA

THE TUNGSTEN SITUATION: PLACER WORK, LEASING, PRICES.

Continued activity marks developments in the most prominent tungsten area of the United States, namely, Atolia in San Bernardino county. The influx of population continues, and it is estimated that there will be a population of 1000 here next spring.

Production of placer scheelite is increasing, and where only a half dozen 'float' diggers were busy in October, there are now 30 at this work. The 'potato patch' is producing daily from 250 to 400 lb. of high-grade (almost pure) scheelite, also about a ton of lower grade. The workmen, mostly foreigners, get $3 per day of eight hours. The high-grade is crushed and dispatched with the regular shipments of concentrate made by the Atolia company.

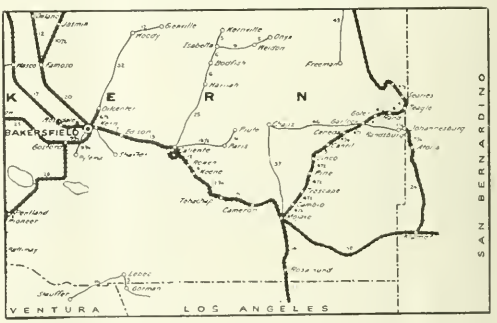
There is a noticeable gain in scheelite production from the 'stringer district,' where both quartz and placer scheelite has created a stir. Nearly 100 men are employed in that area, mostly lessees, who pay as high as $1 per foot for squares of ground averaging 250 ft. of surface. The mineral found is smaller, but the particles are quite as rich as those of the potato patch, four miles south-east.

On the road to Randsburg, and 2½ miles from Atolia, a well known miner named Bob Tate has discovered a small promising, high-grade scheelite vein, which proves that the area of the tungsten belt, in Rand district, is fully six miles long and three miles wide. Engineers who have examined the geological formations of Kern and San Bernardino counties, agree that recent discoveries warrant the prediction that there is a granite belt 30 miles long, extending west from Hinckley on the Santa Fe railway, near Barstow, to Kelsey creek, which gives promising prospects of scheelite, wolframite, ferberite, hübnerite, and even molybdenite. No commercial production of any of the last named are reported so far, but a grayish specimen from the properties recently discovered by Mayhood and Fellman, near Jawbone canyon, is about 40% grade, which shows a mixture of scheelite with a darker mineral, which is probably hübnerite. A mill has been erected on this property, and crushing and concentration of the ore has already begun. Shipments will necessarily include a haul by auto-trucks of 32 miles to Cinco, a station on the Southern Pacific branch, to Owens river. Several Atolia miners have migrated to the new centre with prospects of leasing.

Among new lessees in the Atolia district, are Jim Burns and Dan Connors, who have begun development of Andy Nixon's White Flower claim. C. B. Raymond is a new lessee of Scheelite No. 6, an east extension of the Osdick claims about a mile east of the new Atolia mill. Work here is deep, there being from 20 to 40 ft. of overburden, combining stream-wash, lava, and 'malapai,' before the granite bed-rock is reached. Driving on bed-rock, however, is productive of high-grade scheelite in placer form. A few feet of driving frequently more than pays for the extra cost of sinking. Carl Mengel and A. Kazamoat secured over 500 lb. last week, after striking bed-rock at 30 ft. The large pieces were sharp and angular, showing that the source of this deposit was not far distant. About a score of lessees are now operating on the Osdick properties, on the flat between Atolia and Cuddaback lake.

The recent completion of a new 30 by 60-ft. lodging-house at Atolia has again been augmented by an order for 36 more tent-houses, to accommodate the additional population of the camp. There are now over 250 men on the Atolia Mining Co.'s pay-roll, besides those employed elsewhere by lessees and placer miners. Whereas the pay-roll in 1914 was less than $4000 per month, at present it is over $35,000. Production has increased from 8 to nearly 100 tons per day.

Messrs. Brock and Lypp, successful lessees on Osdick's Skylark claim, sold 13 tons of concentrated scheelite to the Atolia company on November 9; the price stipulated was $42 per unit of 60% WO_3, or better. It is estimated that this lease will net the holders over $200,000 each, before next May, if present prices for tungsten prevail. Prices for placer tungsten dropped



MAP SHOWING THE TUNGSTEN DISTRICT OF ATOLIA.

at Randsburg, and sales were made at $38 per unit by the usual buyers. A further decrease is predicted, as future deliveries cannot be contracted for beyond a few days at a time.

D. Atkins, of Atkins, Kroll & Co., San Francisco, managers of the Atolia properties, was here on November 12, on a tour of inspection, which included an ore-shoot from the Churchill mine No. 1. This ore came from a shaft that is now down over 1000 ft., with good pay ore still going down.

SONORA, CALIFORNIA

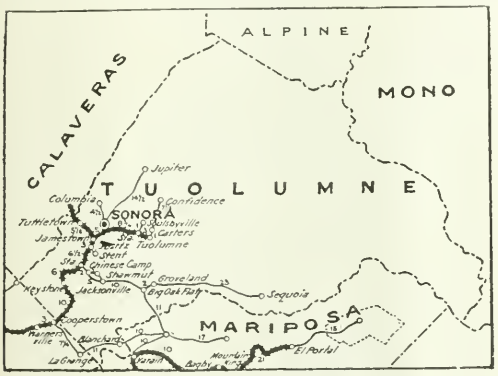
REVIVAL OF MINING IN TUOLUMNE COUNTY; NEW CAPITAL FOR OLD PROPERTIES, AND MORE DEALS PENDING.

It may be said that the outlook for a general revival of activity in Tuolumne county's mineral area is better to-day than at any time in the past 20 years. Capital is seeking investment here in a large as well as a small way, and some of the former mines of note are being re-opened. Within the past month three large Mother Lode properties have been sold under bond, and are being energetically developed. The old Rawhide, a rich producer 20 years ago, is now in the hands of the Silver Peak Mining Co., of Nevada. John Moicene is directing the work of resuscitating the Rawhide, and as soon as the mine has been unwatered, the shaft, which is down 1700 ft., will be sunk to greater depth.

At the Dutch, Sweeney and App, recently acquired by W. J. Loring, of the firm of Bewick, Moreing & Co., of London, a vigorous underground campaign has been started to uncover at a greater depth extensive and rich orebodies which were found and worked out in the upper levels. Great improve-

ments to the surface equipment is being planned, which will be made just as soon as development in the mine warrants them. Mr. Loring feels confident that he will obtain gratifying results in the Dutch-Sweeney-App property. To a representative of the PRESS on November 12, Mr. Loring stated that his English associates are not connected with him in his Tuolumne county enterprise, on account of the War; American capital which Mr. Loring personally interested in the East, is behind the scheme.

The Republican group of five claims, south of the Eagle-Shawmut mine, was the third Mother Lode property to be taken over. F. W. Page, manager of the Royal Consolidated mine at Hodson, Calaveras county, and James T. Currie, manager for an English company owning extensive oil-producing properties in California and Mexico, hold the bond to purchase this property. The Mammoth, one of the group, contains a large



MAP OF TUOLUMNE COUNTY.

body of low-grade ore, which is being mined from the face of a 700-ft. adit. In the Republican a drift is being driven north to cut a vein beneath the Orcutt claim, from the surface of which $75,000 was taken years ago. In extending this drift last week a new vein was cut, of good value. The 20-stamp mill is being overhauled, and will be started on ore from the Mammoth within two weeks.

On the east belt many properties are being examined, and a few deals are about to be made. Lessees at the Live Oak mine, a southerly extension of the Black Oak, and owned by the Black Oak Mines & Mills Co., in widening an old shaft have cut a vein assaying from $55 to $150 per ton. Several tons put through the Black Oak mill yielded $30 per ton. The lessees are A. R. Blackburn, A. C. Macomber, and Harold Stage. Under the terms of lease they are privileged to hold the property for six years, and work it to a depth of 400 ft., and drive in any and all directions within the limits of the mine's boundaries. The owning company will treat the ore extracted at a price a little over actual cost.

DEADWOOD, SOUTH DAKOTA

TUNGSTEN PRODUCTION AND OCCURRENCE.—ORE VERTICALS.

Tungsten ores have during the past few months been receiving more attention from prospectors. The increased prices have naturally stimulated search for the ores, and numerous old veins and many new ones have been developed. In the Hill City district, which appears to be one of the most extensive fields in the Black Hills, over 50 lode-claims have been located in the past few weeks, to cover some of the known outcrops. But the Wasp No. 2 mine, at Flatiron, two miles south of Lead, has made by far the largest production of ore. Since early in the summer, when the first shipment was made, the company has realized over $100,000 for the product which has been marketed. These shipments have consisted of cobbed ore, and have contained an average of close to 50% tungstic acid. A large quantity of lower-grade ore, the result of sorting, has been piled on the dump, and to handle it a concentrating-plant of 25 to 30 tons daily capacity will be installed as soon as the machinery, which has been ordered, is delivered. It now appears that the company's profits from the wolframite will be greater than its net realization from its cyanide-plant. Last month a dividend of 10c. per share was paid, making a distribution of $50,000; this was largely credited to the wolframite production. Previous disbursements this year have been ½c. and 1c. per month.

In the Black Hills are three known areas of tungsten ores, namely, the Lead-Flatiron, Tinton, and Harney Peak pegmatite districts. In the first, which includes the Wasp No. 2, Two Strike, and other properties at Flatiron, and the Harrison, Durango, and others in west Lead, the ore occurs as a replacement of dolomite, at and near the top of the Cambrian quartzite. The deposits lie in a nearly horizontal position, are one foot or so thick, four or five feet wide, and at times are several hundred feet long.

In the Harney Peak pegmatite area the wolframite and ferberite occur in quartz veins and pegmatite dikes, but so far no production has been recorded from the latter. The veins are from a few inches to a foot or more thick, occasionally with a pegmatite or granite wall, but usually enclosed between schist walls. They ordinarily trend in a direction parallel to the schistosity of the wall-rock; there has been but one cross-vein, cutting the strike of the schist, called to the attention of the writer.

In the neighborhood of Hill City, Oreville, Keystone, and Spokane, a large number of veins have been identified, which, while they are small, as has been noted, give promise of yielding a good quantity. These ores are easily crushed, and may be readily concentrated. The quartz veins as a rule produce clean ferberite, with occasional scheelite, and since they contain no pyrite, tantalite, columbite, or other heavy interfering mineral, a good product is made. At Flatiron the ore is fine grained, extremely hard, and tough, necessitating grinding to not coarser than 30-mesh in order to make a good recovery by concentration. The ores are mostly wolframite; scheelite is a rarity, and occurs only in small grains. In the Tinton district the lodes which yielded placer scheelite and wolframite were probably lower grade than those at the other points mentioned; probably the placer deposits are erosion products of large pegmatite dikes containing small quantities of the tungsten minerals.

It appears from present developments that the Heidelberg property, three miles east of Deadwood, is in a region of more than ordinary mineralization and enrichment. In the part exploration of less than 1500 ft. of the ground, five ore-making 'verticals' have been disclosed. (A vertical is a localism of the Black Hills, applied to mineral-filled fissures and fractures cutting the Cambrian rocks, and through which the ore-forming waters circulated. Where the verticals traverse lime-shales and dolomitic rocks, deposits of gold ore have been formed; the verticals themselves are enriched in the neighborhood of these rocks.) The latest vertical to have been discovered gives promise of developing into one of the most important. It had scarcely been followed beyond the surface at the time of the visit of the PRESS correspondent, when already a fair-sized dump of $12 to $15 gold ore had been sorted, and a dump of milling grade established. To cut this seam on its strike some 350 ft. from the surface, a cross-cut is being driven from the main adit. The face of ore was about 4 by 6 ft. In other verticals which have recently, or during the past fall, been identified, the gold-content has not been so great, but additional work on them may at any time reveal ore of better grade. The Heidelberg company is strictly a Deadwood concern. The company is slowly and steadily developing its property to the point where a small cyanide-plant will be necessary.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Placer mining at Fairbanks was reported as finished for the season during the last week of October. The dredge on Fairbanks creek was expected to work until November 1.

Tungsten ore of high grade is reported to have been found in commercial quantities near the head of Gilmore creek. Claims were staked by Albert Johnson.

Opposite 8, 9, and 10 Above, Livengood creek, at Tolovana, J. Allman has opened gravel containing $1.50 per sq. ft. of bedrock, at a depth of 45 feet.

Over $150,000 of antimony ore has been shipped from this district this year.

Juneau

On November 29 the Alaska Mexican, Alaska Treadwell, and Alaska United companies will pay dividends No. 79 of 10c., No. 114 of 50c., and No. 33 of 30c., per share respectively.

It is expected that the Alaska Gastineau company's Annex creek power-plant will be supplying current by December 1. The tunnel to tap the water of Annex lake will be through by January 1. The transmission-line to the Perseverance mine has been ready for some weeks. At the mine there are 650 men and 81 machines working, in charge of B. B. Neiding. The company employs 1300 men in all, the last pay-day being $150,600.

A mine-rescue corps has been organized at Treadwell.

At the Chichagoff quartz mine near Sitka, an addition of five stamps and a tube-mill has increased the daily output to 110 tons. James L. Freeburn is superintendent for the owners at Tacoma, H. P. Wallace and W. R. Rust.

ARIZONA

Bulletin No. 3, mineral technology series No. 1, of the Arizona State Bureau of Mines, is a directory of Arizona minerals. About 110 minerals are given, with brief notes on their occurrence and locality.

Manganese ore is found in certain mines of the Tombstone district, Cochise county; the Clifton-Morenci district, Greenlee county; 30 miles south of Wickenburg, Maricopa county; at Salome in Yavapai county, and in the Mohawk mountains of Yuma county, according to P. E. Joseph in Bulletin 4, Mineral Technology Series 2, of the State Bureau of Mines.

Discussing what is known in this State as the Eighty Per Cent Law, *The Copper Era* of Clifton says the following, in part:

"As expected, the law initiated in Arizona at the last election has been declared unconstitutional by the United States Supreme Court on the broad ground that it was in violation of the Fourteenth Amendment. The case went to the Court from Cochise county, and was commenced by a foreigner who had been discharged under the provisions of the new law, which prohibited the employment by any employer of more than 20% of employees who were not qualified electors. The Court ruled that no State has the right to prohibit a person from earning a livelihood after that person has been legally admitted into this country under the immigration laws of our own making."

Cochise County

The Grace Dodge Memorial Home, at Bisbee, the gift of the Copper Queen Mining Co., was opened on November 19.

Gila County

A bond issue of $350,000 for better highways in this county was approved by election at Globe, Miami, Hayden, Winkelman, and other centres on November 15. This improvement will be of value to the mining community.

Greenlee County

In an editorial in its issue of November 12 *The Copper Era* of Clifton has the following, in part:

"Two months have passed since the employees of the three large mining companies in the district obeyed the strike order of Western Federation of Miners organizers.

"With the exception of the electric-light plants, not a wheel has turned since that time in the entire district; approximately 5000 men have remained in idleness, and at the end of the 60-day period the financial loss to each and every one is being keenly realized. Already the loss in wages alone is $1,000,000 and the loss to the mining companies is several times that amount, while the independent business man, together with his force of employees, has been proportionately affected.

"The outlook for an immediate settlement of the strike is not hopeful to say the least, unless perchance, Hywell Davies, of Lexington, Kentucky, the official conciliator of the Department of Labor, who is now in El Paso, may work out some plan which will be acceptable to employers and former employees. In the beginning, however, Mr. Davies makes it plain that he has not come to the Southwest as a mediator.

"At the end of the second month, as it was in the beginning, the stumbling-block between the former employees and the mine managers is the Western Federation and its organizers. Both sides are fully alive to the significance of the result of the labor troubles in this district, and unfortunately for all concerned, the indications are at the present writing that the contest will go to a finish, and the Clifton-Morenci district has been selected as the battle-ground.

"The duration of the strike apparently depends now on the determination of the mine managers to stand by their last statement, and the ability of the Western Federation to secure sufficient financial assistance from allied organizations to prolong the struggle indefinitely. Such is the situation. Gloomy, to say the least."

Mohave County

The first annual meeting of the United Eastern Mining Co. was held at Oatman on November 17.

The election of officers resulted as follows: president, Frank A. Keith; vice-president, G. W. Long; treasurer, R. I. Rodgers; secretary, Wallace Keith; directors, the above named with D. C. Jackling, Seeley W. Mudd, Ralph C. Nowland, W. K. Ridenour, Philip Wiseman, and J. L. McIver. A detailed report of the property will be published in the near future. Developments have been very good. The new shaft is to be sunk at once. Machinery has been ordered for the new 200-ton mill; it will consist of gyratory crusher, ball-mills, tube-mills, and Dorr continuous-decantation plant. The ore in the ball-mills will be crushed in cyanide solution. George W. Long is superintendent.

Yavapai County

Good rains have stimulated mining in this county. Four new mills have been waiting for water, and can now start. Placer work is increasing.——On Lynx creek the Lafayette Placer Co.'s claims have been sold to Wichita, Kansas, people,

headed by C. S. Israel. A dam for hydraulicking is to be built. ——On Slate creek the Dunkirk mine has sent its 14th car of copper-silver-gold concentrate to Hayden. Flotation is used here.

Tungsten ore has been found in the Eureka district, and prospectors are busy looking for more deposits.

At the Major company's Eureka mine in the Walker district, 20 men are employed, and ore is being shipped. A plant, including a Lane mill, tables, and flotation is proposed.

CALIFORNIA

Calcined magnesite is now quoted at around $30 per ton. In 1914 the quantity consumed in the United States was 122,000 tons of calcined and 13,000 tons of crude imported, and 11,293 tons of raw domestic, equivalent to a total of 132,000 tons of calcined magnesite. Austria supplied 93%, Greece 3%, and California the balance of 4%. Owing to the War the sources of import are practically closed, and the output of California, the only producing state, can not nearly meet the demands. The best magnesite comes from mines near Livermore, Alameda

MAP SHOWING DISTRIBUTION OF MAGNESITE DEPOSITS IN CALIFORNIA; THE BLACK DOTS REPRESENT THE DEPOSITS.

county, while one in Sonoma county yields a good refractory product, in demand by steel makers for their furnaces. The accompanying map, showing the situation of magnesite deposits in this State, is from the U. S. Geological Survey report by Charles G. Yale and Hoyt S. Gale.

According to the State Mining Bureau, the new work of the Bureau in protecting the oilfields against underground water is progressing satisfactorily. The appointment of practical oil men as deputies in the fields has been thoroughly appreciated. Owners are all in favor of the work and are beginning to send in the necessary information. A few months more will see the system fully understood by all operators. The nature of information necessary for this work calls attention to the fact that the producing of oil is now considered more as a business than a gamble. Formerly men would spend thousands of dollars in drilling wells, and would have no record of their condition or method of drilling, and would also continue operations without recording the productiveness or behavior of the various wells. The same men would not have thought of investing money in another line of business without a complete inventory and regular accounting. The logs of wells and monthly production reports required by the Bureau for its work are of even greater value to the operators furnishing them. General realization of these facts accounts for the hearty co-operation of the operators with the Bureau. A list is given in a press bulletin of drilling new wells, deepening or re-drilling present wells, and tests of water shut-off.

Amador County

The following is the preliminary report of the output and costs of the Plymouth Consolidated for October:

Ore milled, tons	11,000
Total value	$54,499
Workings expenditure	29,301
Development charges	3,328
Surplus	$21,870

According to W. J. Loring, the Plymouth Consolidated is controlled by an English company, and of its 240,000 £1 shares, 60,000 are held by Americans. The company spent $830,000 of English money up to the time that milling began. From August 1, 1914, to October 1, 1915, the gross yield was $686,073, with a profit of $218,030. The mine is equipped with 30 stamps. A total of 141,623 tons was treated during the above period. The average duty per stamp at the present time is between 11 and 12 tons, and the recovery is a fraction under 90%. The total cost, including development, which is a heavy charge, amounting to $6000 to $9000 per month, is less than $2.90 per ton. James F. Parks is manager.

Butte County

(Special Correspondence.)—Statements have been made recently to the effect that there is a boom in mining around Forbestown, whereas in reality nothing has been done on which to base a boom. Many men come here looking for work on the strength of these reports, and find no openings. There is a great deal of low-grade sulphide ore in some properties, but the owners will not sell at reasonable prices, hence the place is quiet.

Forbestown, November 16.

The Triumph mine at Lumpkin is to be re-opened by F. A. Thompson, after being idle for several months.

Eldorado County

According to Burr Evans in the *Placerville Republican*, the pay gravel of the buried river channels is cemented in some places, necessitating crushing by stamps; in other places, as at the Rising Hope mine, three miles from Placerville, the gravel is loose, making treatment easier. The latter has been washed as in ordinary hydraulicking, but with heavy losses of fine gold. A barrel gravel mill is now working at this mine, making a good recovery. Its first cost is low, and it does not crush the gravel, simply disintegrates and washes it. The fine material is then run over riffles and shaking-tables. This 5 by 3½-ft. machine treats six tons per hour. The amalgam from the table is retorted as usual.

The Eureka slate quarry, near Placerville, is being prepared for production. Towers are being erected for the tram that carries the product across the American river to within two miles of Placerville. The quarry was idle for five years.

Four miles below Placerville the Webber Creek Dredging Co. is to commence dredging this week. Twenty men are employed.

Mariposa County

The Fremont grant has been inspected by E. H. Benjamin, president of the Mariposa Commercial & Mining Co., owning the area, and W. C. Ralston, well known in this State, in company with F. T. Maguire, the resident manager. They examined the condition of the various mines, as negotiations for the purchase of the property are well under way, and a new company, composed of Eastern capitalists, is being organized to operate the mines, which is expected to be at an early date. It is at the Mariposa mine that these men have their hopes for successful operation of the property.

It is well known in connection with this mine that it has paid dividends from $2000 to $20,000 per month. Mr. Ralston

expressed surprise that the mine was allowed to close down. The shaft is 1600 ft. deep, and the workings confined to levels only a few hundred feet in length, both east and west. The buildings are in bad condition, the large boilers and other machinery are off their foundations, and exposed to the elements, shaft is also caved from the collar to a considerable depth.

Shasta County

Good ore has been cut at 1300 ft. in the Gladstone mine at French Gulch; this is 100 ft. lower than before. A drift 700 ft. long had to be driven to cut the vein. A bonus was given to the miners for fast work. The general manager, J. O. Jillson, estimated that ore would be cut by November 11 or 15, and this was done on the 14th. E. L. Young is superintendent.

Sierra County

The 10-stamp mill at the Red Ledge mine at Alleghany is ready for crushing; plenty of ore is broken for it. B. James is in charge.——At the Croesus company's Oriental mine the 10-stamp mill is almost ready. At its Plumbago mine 15 stamps are dropping.——At the Tightner the deepest work in the district is being done.

Siskiyou County

(Special Correspondence.)—Mining is fairly active in the Salmon River district. The late rains have provided sufficient water to start hydraulicking at several properties, and the season promises to be an active one. The Van Brunt, Siskiyou, and other large properties have been placed in shape for extensive production, new flumes built, and additional ground developed. Quartz mining also shows progress. The Big Cliff Mining Co. is increasing its working force, planning new developments, and preparing to install a good deal of machinery. The orebodies are large and of good-grade. The Siskiyou Syndicate has purchased a mill for its Cub Bear mine, and is endeavoring to place it in commission before much snow arrives. Arrangements have been made for vigorous developments during the winter. Work will also be continued at the Blue Jeans, and other mines. Large quantities of wood have been stored at the Black Bear mine, for the steam plant, and a campaign of aggressive developments has been decided on. It is stated recent prospecting in the property has opened promising territory.

Discoveries of manganese in the western part of Siskiyou county are attracting much interest. Representatives of the U. S. Steel Corporation have examined a promising deposit in Callahan gulch, near Sawyer Bar, and other properties in this section are receiving attention. As the road conditions in this district are not satisfactory, a movement has been started to improve the highway from Etna Mills to Orleans, from which point crude ore could be sent to Eureka for shipment by water. A good road would also encourage gold mining in this district, as several properties are idle largely because of heavy transportation costs.

Etna Mills, November 15.

COLORADO

Clear Creek County

(Special Correspondence.)—A two-foot shoot has been cut on the Boulder Nest vein, intersected 2000 ft. from the portal of the Commodore adit on Red Elephant mountain, and a recent carload shipment was settled for $140 per ton in gold, silver, and lead. The ore has been stripped for a length of 20 feet.

The Climax property on Columbia mountain is being developed, operations being carried through the Leasch adit. A well mineralized vein is now being opened. J. R. Calden of Denver is manager.

A deal is now pending whereby the Princess of India adit will be consolidated with the American Sisters property. Both are situated on Columbia mountain, and it is proposed to extend the adit under the flat to cut the American Sisters vein. J. J. White of Georgetown is owner.

An orebody, two feet wide and assaying 225 oz. silver per ton, has been opened in the Albro mine on Albro mountain. The vein was opened by a cross-cut, and was reached at an increased depth of 250 ft. under the shaft workings. Earl Dingle of Dumont is the lessee.

The Q. D. L. Leasing Co. has started work on the East Lake mine on Bellevue mountain. Work is done through the Big Five adit; a winze is to be sunk 100 ft. to undercut the Mosher ore-shoot that has been yielding about $10,000 per month for more than a year. G. K. Kimball is manager.

Idaho Springs, November 16.

Lake County (Leadville)

The rise in price of silver has given a better tone to producers of that metal at Leadville.

The Western Zinc Oxide Co.'s plant is working full time, receiving plenty of carbonate ore and making a good product.

Water in the Penrose shaft is down about 690 ft. The old levels are being cleaned out and repaired.

Ouray County

The Wanakah smelter is to be moved from its present site to one just south of the mill. About $2000 per month will be saved in freight, handling, etc.

San Juan County

The Yukon mill on Cement creek, near Silverton, is to be rented by the Colorado Metal Co. for the treatment of tungsten ore from the Dawn of Day mine near Gladstone.——The Mears-Wilfley mill is closed until next spring on account of the cold weather. Flotation has been very satisfactory at this plant.

Teller County (Cripple Creek)

Lessees at No. 5 level of the Empire State shaft of the Isabella property have opened a new shoot in the Mahoney vein, 24 to 30 in. assaying $25 to $30 per ton. This vein was thought to be worked out.

At the Elkton the shaft is down 73 ft. below No. 16 level. Water is receding at the rate of 16 ft. per month. Over 25 sets of lessees are working, and the output in October by them and the company was 1800 tons.

The old Rhinocerous and Nil Desperandum claims on Raven hill have been leased to H. M. Roeschlaub of Denver.

IDAHO

Shoshone County (Coeur d'Alene)

According to *The Wallace Miner*, the absence of transportation facilities in several areas of the Coeur d'Alene region in which there is great and ever increasing mining activity, and in which actual tonnage for a railroad is ready for extraction, is responsible for the idea that next year will witness the construction of at least one branch railroad and possibly more. There are rumors that the Chicago & Milwaukee is also preparing to enter this field, particularly the ore haul from the mines to the Northport smelter, in Stevens county, Washington. That the O.-W. R. & N. railroad would eventually build up Beaver creek from its north fork branch has long been regarded as certain, the company simply waiting until the mines of that rich area have reached a point of development that would ensure plenty of ore. The time has now arrived when such a line is a necessity, and it is thought that the O.-W. R. & N. will enter that field in the spring. The Interstate-Callahan will undoubtedly in time change its outlet to Beaver creek, and is supposed to have had that in view when it secured a mill-site on the north fork. The Tuscumbia is already a shipper, and also the Idora, while the possibilities presented by the Sunset, Portland, Beebe, and numerous other properties which promise large tonnage at no distant date certainly present a field for profitable business that no railroad company can afford to ignore. With such a showing it is a safe prediction that next summer will witness the construction of a railroad from the North Fork up Beaver creek to the base of Sunset peak.

According to reports from Pine creek, that area was visited last week by a representative of a railroad company, evidently for the purpose of gaining first-hand information regarding the quantity of ore blocked out. The rapid strides now being made in the development of these mines justify the attention they are receiving from the railroad companies. Already ore shipments from Pine creek have reached a point of considerable importance, and one mine, the Highland-Surprise, is now in position to make regular shipments of concentrate. The plans for the development of the Constitution include the erection of a mill in the spring, and the same is true of the Amy and Matchless. The Little Pittsburg is preparing to make shipments, and numerous other properties are rapidly approaching the productive stage. The fact that Pine creek is without transportation facilities has been a serious drawback to its development, but in spite of this handicap its enterprising operators have demonstrated that it is a profitable field for a railroad, and its construction would at once give an impetus to mining that would soon make the Pine creek branch a valuable addition to the railroad system of the district. Pine creek should have a railroad next year.

MICHIGAN

The Copper Country

The last bi-monthly pay-day in this region was on November 13, when approximately $700,000 was distributed, one company paying $230,000. The present annual wages are at the rate of $17,000,000.

At the White Pine Extension property, forest is being cleared, a 4½-mile wagon-road constructed to Nonesuch, machinery has been ordered, and foundations for 11 buildings completed. The buildings are to be of corrugated iron on the outside, lined inside with fire-proof plaster board and plaster; all will be steam heated and electrically lighted. A turbo-generator will supply current. Work on the new shaft will commence early next year. Over 100 men are employed.

MISSOURI

Jasper County

According to an address given by U. S. James of Newark, New Jersey, before the Southwest Missouri Mine Safety and Sanitation Association at Webb City, Joplin millmen are not getting the best results from slime treatment. He discussed rolls and table work.

On a lease of the Squires land at Galena, T. Tarr is erecting a tailing-mill of 750-ton capacity per shift. It will treat a large dump at the Squires custom-plant, which contains 3.5% blende. According to the *Joplin News Herald* an interesting feature of the mill is the installation of Dorr thickeners, the only ones in the district, to be constructed of concrete. They are circular in form, the sand thickener being 18 ft., and the slime thickener 30-ft. diameter; each is six feet deep. A Miller gas-engine of 135 hp. will be used to drive the mill, the equipment of which consists of two 36 by 48 rougher jigs and one 30 by 52 cleaner jig; seven elevators, five screens, two sets of 30-in. rolls; 11 tables, arranged as follows: one Butchart system Wilfley rougher, ordinary Wilfley rougher; four sand-tables; one finishing sand-table, three slime-tables, and finishing slime-table. Concentrates are drawn for the shipping bin only from the two finishing-tables, and from the cleaner-jig.

MONTANA

The State compensation act has been in force three months. Of 1289 accidents, 20 were fatal. Total benefits paid were $24,865. Of the 1289 accidents 596 are attributed to the negligence of the employees; 40 to the negligence of the employer; 77 to the fault of a fellow employee; 47 to a defect in a machine, and 528 are accounted unavoidable. Sixty-seven per cent of all the accidents occurred in the mining industry; there were 10 fatal accidents in mining, five at the smelters, two on electric railways, two in power-plants, and one in a coal mine.

Under plan No. 1, 21,625 employees are insured. The total annual pay-roll is $25,457,711. There was paid out during the first quarter, $23,489. Under plan No. 2, 10,841 employees are insured. The annual pay-roll totals $8,363,188. There was paid out $1,306. Under plan No. 3, 2170 employees are insured. The pay-roll totals $369,069. There was paid out $157.

The commissioners' report states that if the proportion of accidents continues the same throughout the year, 20 out of every 100 men in the mining industry will be injured, 12 out of each 100 in the smelting industry, and 10 out of every 100 in the lumbering and logging industry.

Lewis and Clark County

During the four weeks ended October 15, the Franklin mine in the Scratch Gravel district, owned by the Thomas Cruse estate, made a profit of $25,493; and from December 20, 1914, to that date the profit was $162,476. At the Cruse mine at Marysville, operations from December 20, 1914, to August 15, 1915, left a loss of $40,686. Work may be suspended.

NEVADA

Clark County

(Special Correspondence.)—The Goodsprings district is very busy, about 400 miners being employed, and 28 properties are shipping ore, mostly zinc, also some lead. The output in July was worth $250,000 gross, so the present value may be figured from that. Water is scarce here, it being hauled by rail and then delivered by auto-trucks to the mines, 18 miles in one instance. This necessitates dry treatment of the ore, the Stebbins dry concentrator being used, giving a good separation. The ore is a carbonate of zinc in dolomite, with some galena; sphalerite is rare. The Bullion, Frederickson, and Yellow Pine have mills. The Mobile mine produces 120 tons of crude ore per month. It is controlled by the Walkover Shoe Co., of Boston. W. S. Black is superintendent. Over a good road, eight miles long, the district's products are carried to Jean on the railroad, for shipment to Kansas smelters.

Goodsprings, November 17.

Humboldt County

At a distance of 1350 ft. from the entrance of the Friedman adit, a vein was cut on November 13, which, up to the 16th, was 34 ft. wide, with the face still in ore. The best ore is on the foot-wall, the last 15 ft. assaying from $6 to $20 per ton.

According to L. A. Friedman of the Rochester Mines Co., the orebody was cut at 1342 ft. from the portal of the adit. Up

PRESENT CONDITION OF ROCHESTER MINES PROPERTY.

to November 20 the lode was 45 ft. wide. It may be termed a contact vein, with an andesite foot-wall and a rhyolite hanging wall, lying almost flat. For 21 ft. it was worth from $1 to $6 per ton. At this point a quartz vein came in, at an angle of 45°. This is from 8 to 10 ft. wide, and assays from $6 to $20. The last sample taken from across the greater portion of the vein gave $7.20 in gold and $5.45 in silver. The adit will be driven to the 1500-ft. point. After that raises will connect with the orebodies between the 400 and 600-ft. levels, below the bottom of the winzes. Winze 301 is in 26 ft. of ore, worth from $10 to $30, with occasional $90 assays. Winze 302 is in 10 ft. of ore of similar value.

At a depth of 1500 ft., in the winze at the Seven Troughs Coalition mine, the vein has been cut, showing a good and wide body of ore.

Mills in the districts contiguous to Lovelock are the Seven Troughs Coalition, with a monthly output of about $60,000 (for November); Rochester Mines, $60,000; Lincoln Hill at Rochester, $5000; and Darby at Mazuma, 50 tons of $20 ore daily. The new Nevada Packard at Rochester will soon be yielding $1000 per day, while the St. Anthony Mines Co.'s tungsten plant at Toy is treating 50 tons of ore per day, its value being variable.

Esmeralda County

The preliminary report on the Jumbo Extension October output is as follows: ore shipped, 3476 tons; gross value, $112,000; sampling, freight, and treatment, $32,000; smelting losses, $14,000; mining and development charges, $16,000; and net realization, $50,000.

Experiments to treat the copper-gold ores of the deeper workings of the Goldfield district have been under way for some time, and it is announced, according to the *Tribune*, that a 30-ton flotation-plant will be erected at once at the Goldfield Consolidated mill. A statement to this effect appeared in the Press of October 9.

At a point in the north drift of the 1750-ft. level of the Atlanta, where 5½ ft. of $40 ore is showing, and farther along the drift 15 to 20 in. of $70 ore, a winze has been started. This work is of great interest.

Lincoln County

The Prince Consolidated company at Pioche is shipping 400 tons of ore daily, with good profit. Development is said to have disclosed a large quantity of ore.

Lyon County

It is reported that the Mason Valley company's smelter and leaching-plant at Thompson will resume work early in December.

Mineral County

A good deal of tungsten ore is being produced by C. E. Noble at Sodaville, who employs 35 men. The ore is shipped to San Francisco.

Nye County

Companies and lessees at Tonopah last week produced a total of 10,093 tons of ore worth $207,634.

In October the Belmont mill treated 12,342 tons of ore yielding 208,058 oz. bullion, with a profit of $65,069.——The Tonopah company's plant treated 12,435 tons averaging $12.80 per ton, with $60,700 profit.——The Extension profit was $66,000.——From 4604 tons the Jim Butler profit was $27,067.

White Pine County

(Special Correspondence.)—Tungsten mining is increasing in activity in the county, a lot is being found, and many new locations are being made, about 30 men locating near Osceola. Several engineers are investigating the areas. Three mills are working, and a fourth being erected. The mineral is found for over 100 miles. In Snake range, a discovery of scheelite has been made in Big wash, 10 miles south of Snake creek, which is eight miles west of Garrison, Utah. The owners are packing high-grade ore off the mountain, 9000 ft. altitude, with burros. Chapman and Taylor, for a San Francisco company, are operating at Snake creek and Sacramento pass; cold weather and snow interferes with their mill work. The U. S. Tungsten Co. is employing over 100 men south of Osceola. It is reported that one can sell a 65% product for $45 per unit. The old Victoria copper mine in Dolly Varden district, 15 miles north-east of Currie, on Nevada Northern railroad, is making regular shipments.

Ely, November 15.

NEW MEXICO

Grant County

The Carlisle property of G. H. Utter at Steeplerock has been sold to New York people for $300,000. The mine is opened to 637 ft. and has produced a good deal of ore.

OKLAHOMA

Ottawa County

After doing 40,000 ft. of drilling in its land at Picher during the past two years, the Picher Lead Co. decided to erect four large mills, the first of which, of 300-ton capacity, commenced work last week. It is motor driven throughout. The total quantity to be treated by the four plants will be 1400 tons per 10-hour shift.

UTAH

Piute County

Five miles north of Marysvale another deposit of alunite (potash mineral) has been discovered. It is under a cap of iron ore, which has been mined to some extent. The alunite assays 9% potassium sulphate. Development of other deposits south-west of Marysvale is encouraging. The Mineral Products Co.'s new mill is working well, producing a good grade of potash.

Summit County

Park City mines shipped 1295 tons of ore last week.

A centrifugal pump of 1000-gal. capacity per minute has been ordered for the Ontario silver mine, to be installed at 1700 ft. The property is now drained to the 1500-ft. level by the Ontario adit, which is used to drain most of the properties at Park City.

WASHINGTON

Grays Harbor County

(Special Correspondence.)—Twenty-five miles from Aberdeen five outcrops of manganese ore have been uncovered in the Olympic forest. Some of the ore assays up to 58% manganese and 4% silica. A market is being sought for the product.

Aberdeen, November 20.

Stevens County

Spokane people are to revive the old Deer Trail district, 25 miles west of Springdale, as modern methods should result in profitable work. The Deer Trail mine is said to have yielded $3,000,000 from 1893 to 1902, and the present owner, the Deer Trail Mining & Development Co., in charge of A. Robinson, is to erect a 75 to 100-ton mill driven by oil-engines. The mine is developed by adits to a depth of 900 ft. Stopes and dumps are estimated to contain 250,000 tons of $7 ore.——The Silver Basin mine has also been extensively opened, and work will be resumed early in December. The output is about $300,000. Freight and treatment at smelters cost $11 to $20 per ton.——The Silver Hoard claims have been under development since September 1, with good results. A mill is proposed.

At the Laurier mine near Colville, a 1½-mile tram has been laid from the mine to the station at Laurier. Shipping to Greenwood is to commence. Dumps contain 20,000 tons of ore assaying $10 to $40 per ton in zinc, copper, and gold. G. Stewart is manager.

The Kettle River field, just south of the international boundary, is being actively developed.

In September the United Copper company at Chewelah made a profit of $4423; November earnings are expected to be over $25,000. The 74 stamps are crushing 225 tons per day. Flotation is used, and the recovery is from 77 to 80 per cent.

WISCONSIN

Grant County

(Special Correspondence.)—New producers at Platteville during the past 30 days are the Star, Climax, Kistler, Big Bills, M & H, and Lucky Three. A new electro-static plant is called the Enterprise. The Hodge, Acme, Homestead, Grant County, Crnson, East End, Klar-Piquette are all operating steadily.

At Cuba the National Zinc Ore Separating Co. is treating

800 tons crude concentrates per week and shipping an average of eight cars of high-grade refined concentrate. Campbell Separators are shipping two cars high grade weekly. Utt-Thorne Co., Anthony, Rainsbeck, Gritty-Six Dominion Zinc Co. are all new producers.

At Hazel Green the McMillan Mining Co. is working three shifts on a capacity shaft, 9 ft. of solid milling area was cut from 61 to 70 ft. A new plant is partly complete. Service is set for December 1.

Platteville, November 10.

IOWA COUNTY

(Special Correspondence.)—At Highland the New Jersey Zinc Co., after a drilling out program has ordered a two-cage shaft sunk and will remove the plant in use at the Kennedy mine to the new Eberle ranges.

Three new power and milling plants are being constructed at Linden, one each on the Gilman, Optimo No. 3, and Stoner mines. Milwaukee capital is flowing into this district.

The O. P. David mine, at Montfort, after a two years' shutdown is now on a producing basis.

Freer buying of late has awakened the Mifflin district, which is now shipping 15 to 25 cars of zinc ore weekly. The Coker mine alone delivered 41 cars to the Mineral Point Zinc Co. in October. This mine has been going steadily for 30 years; 12 consistent producers are found here.

The Lucky Five Mining Co., at Dodgeville, disposed of 300 tons of zinc ore last week to the Picher Lead Co.

Highland, November 10.

CANADA

BRITISH COLUMBIA

A tube-mill and cyanide-plant are being erected at the Relief mine near Erie, at a cost of over $20,000. A. D. Westby, the manager, states that the 10-stamp mill recovered 65%, and 90% is expected from the new equipment. About $100,000 of old tailing is to be treated.

During the 10 months ended October 30 the Trail smelter has received 399,070 tons of ore, against 325,631 tons in 1914. The Rossland district is responsible for most of the gain, while Nelson, Slocan, Ainsworth, and East Kootenai show decreases. Work on the new electrolytic zinc plant at the Trail smelter is being hurried. Current for the plant will be supplied from the Bonnington Falls station of the West Kootenai Power & Light Co. It is estimated that the energy required will be from 8000 to 9000 horse-power.

ONTARIO

(Special Correspondence.)—By next spring the gold production of Ontario is expected to exceed the output of silver. This will be due to the increased quantity of ore being milled, notably at the Hollinger, Dome, McIntyre, and Vipond mines. The smaller producers at Porcupine and Kirkland Lake will help. The Tough-Oakes at Kirkland Lake has paid its first dividend, three years from the day actual mining started. This much-advertised mine is doing better than some of its critics anticipated. The workings are now down to 500 ft., and the No. 2 vein maintains its high grade, as well as its width. The Teck-Hughes, control of which was recently acquired by the Buffalo Mines of Cobalt, is being equipped with a 60-ton mill, employing the counter-current decantation system. The work is in charge of Tom R. Jones. An option on the claims of the Kirkland Lake Goldfields, one of the boom flotations foisted in London, has been taken by Frank L. Culver of the Beaver Mines of Cobalt. Prospects at Kirkland Lake are considered excellent.

Cobalt, November 20.

During October the Alexo nickel mine at Porquis Junction, shipped 800 tons of ore to the Mond Nickel Co.'s plant at Conniston.

KOREA

The October clean-up of the Oriental Consolidated resulted in a return of $135,500.

PERSONAL

W. L. AUSTIN is here.

J. R. FINLAY has returned to New York from Butte.

H. W. ALDRIDGE is at the Inspiration mine, in Arizona.

E. V. BRAY sailed for the Celebes by *Shinyo Maru* on November 20.

J. H. HEDGES has moved to Long Beach, Cal., from Nacozari, Mexico.

W. J. LORINO has decided to make his headquarters in San Francisco.

D. W. BRUNTON came to San Francisco from Vancouver, on his return to Denver.

THOMAS CHALMERS, of Chalmers & Williams, was in San Francisco for a few days.

NELSON DICKERMAN, manager for the Pato in Colombia, has been taking a holiday in California.

WILBUR H. GRANT has returned from Octave, Arizona, and will leave next week for Forest City, California.

TAKESHI HIRABAYASHI, chief mining engineer for the Japanese government, visited the Joplin district recently.

H. R. VAN WAGENEN, now in charge of the Consolidated Nevada-Utah mines, at Pioche, is visiting the Exposition.

H. H. COLLEY, assistant-superintendent of the Douglas smelter of the Copper Queen company, is visiting Grass Valley.

CHARLES A. O'CONNELL, manager of the Tough-Oakes mine, at Kirkland Lake, is visiting San Francisco, his former home.

GEORGE M. COLVOCORESSES, general manager for the Consolidated Arizona Smelting Co., was in San Francisco this week.

F. W. MCNAIR, president of the Michigan College of Mines, will be in Los Angeles on the 29th, going from there to Salt Lake City.

SAMUEL W. COHEN, manager of the Crown Reserve mine, Cobalt, has been examining the Globe mine at Dedrick, in Trinity county.

OSCAR H. HERSHEY, FRED T. GREENE, and FRED SEARLS, JR., are giving expert testimony in the Alameda-Success case at Wallace, Idaho.

MAURICE W. BACON has resigned as manager for the Stewart Mining Co., at Kellogg, Idaho, being succeeded by WILLIAM BEAUDRY, the former superintendent.

Schools and Societies

The Southwest Missouri Mine Safety and Sanitary Association has a membership of about 100.

On November 23 the Carnegie Institute of Technology, Pittsburg, will celebrate the 80th birthday of Andrew Carnegie, and the 15th anniversary of the Institute.

The annual meeting of the Faraday Society was held in London on October 19. The following were elected to serve for the year 1915-16: president, Sir Robert Hadfield; vice-presidents, K. Birkeland, Bertram Blount, W. R. Bousfield, F. G. Donnan, Eugene Haanel, A. K. Huntington, and T. Martin Lowry; treasurer, F. Mollwo Perkin; and council, W. R. Cooper, C. H. Desch, J. A. Harker, Emil Hatschek, Cosmo Johns, Alfred W. Porter, E. H. Rayner, A. Gordon Salamon, George Senter, Cav. Magg. E. Stassano. At the 66th ordinary meeting on the same date, the time was devoted to a general discussion on 'The Transformations of Pure Iron,' introduced by the president. 'The Transference of Electricity by Colloidal Particles,' by F. Powis; 'Electrolysis of Nitric Acid, Sulphuric Acid, and Orthophosphoric Acid, Using a Gold Anode,' by F. H. Jeffery; 'The Electrolysis of Concentrated Hydrochloric Acid using a Copper Anode,' by F. H. Jeffery; and 'The Thermal Decomposition of Hydrogen Peroxide in Aqueous Solution,' by William Clayton, were taken as read.

THE METAL MARKET

METAL PRICES.

San Francisco, November 24.

Antimony	40
Electrolytic copper	20.75
Pig lead	5.50—5.70
Quicksilver (per flask)	$105
Spelter	21
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, November 24.

Antimony: 50 and 60% products, per unit	$ 2
Magnesite: calcined, per ton	30
Manganese, 50% metal, 8% silica, per ton	12
Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot	$35—10

New York, November 19.

Antimony: prompt shipment from South America (paid) $2.35.

Tungsten: 60%, $45 paid for prompt; forward delivery done at $41; second half of 1916 quoted at around $35.

Vanadium oxide: no activity reported.

Manganese ore: no activity reported. About 16,000 tons of Indian ore is en route to an eastern Pennsylvania steel company.

Molybdenite: 90% MoS_2, per pound, $1.50.

There is a large difference in the price of tungsten between New York and London, the latter being much lower.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 24.—Copper is firm owing to very heavy buying; on account of foreign demand lead is firm; zinc is strong and active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

Sharp advances characterize the silver market in New York and London, although sterling exchange remains rather weak. Pixley and Abell state that the volume of business is much the same, the firm tone being largely due to reduced American supplies, although China and Europe have been daily buyers. India bought lightly, but stocks at Bombay are heavy. Samuel Montagu & Co. write in a similar strain. The silverware trade in the East and England is much better than for some time.

COPPER

Prices of electrolytic in New York, in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Date.		Nov. 11	100.00

Tin is quiet at 39 to 40 cents.

ALUMINUM

No. 1 aluminum, 98 to 99% pure, is quoted at 58 to 60c. Some desultory sales are reported, but the scarcity continues.

The Department of Commerce at Washington, D. C., reports the following metal exports during the 9 months ended September 30: Copper and manufactures, $83,900,000; iron and steel manufactures; $251,100,000; and zinc manufactures, $21,500,000; against $95,600,000, $152,800,000, and $3,200,000. Imports were: copper in ore, $10,000,000; copper manufactures, $22,000,000; and iron and steel manufactures, $14,800,000; compared with $9,500,000, $23,700,000, and $22,900,000.

Eastern Metal Market

New York, November 19.

A large business has been done in copper, a continuance of the movement previously reported. Large inquiries indicate sustained activity, and 20-c. copper is looked for. Foreign stocks are diminishing, and the London market is higher. Zinc has been active, and prices have mounted rapidly. War contractors and the galvanizing trade both have been large purchasers. Galvanized sheets are higher; sheet-zinc went to 20c. The leading producer of lead is credited with large sales on foreign account, and its price again has been advanced. Fear that Great Britain would close the Suez Canal gave tin consumers and dealers a scare, and they bought heavily at advancing prices. The fright seems to have been without cause, but the small stocks here will serve to keep quotations fairly strong. Antimony is up to near 30c. Not only is the supply small, but it is reported that Great Britain will attempt to control its marketing by imposing regulations similar to those laid down for tin. Aluminum is higher.

The United States Steel Corporation, which sells abroad as the United States Steel Products Co., withdrew quotations in foreign markets last week. Practically all of the steel companies are sold out for several months ahead. Meanwhile the demand shows no sign of lessening, and a steel famine is not at all an improbability. Purchasing has not been halted by sharp advances in prices. In the end the market will fall of its own weight. The nominal quotation for plates, shapes and bars is 1.70c. Pittsburg.

COPPER

The buying of copper, both on domestic and foreign account, has been heavy during the past few days. Prices have advanced to 19c., cash, New York, or 17.87½c., 30 days, delivered, the latter being the usual terms on which electrolytic is sold. Most of the trading was in electrolytic, inasmuch as the Lake companies are well sold up for the next few months, and many of them have withdrawn from the market. The nominal quotation for Lake is 19c. The higher prices caused domestic buyers to become active, but the bulk of the business done was on the part of war contractors. It is an interesting fact that, as intimated last week, many of the recent purchasers of copper are greenhorns at the business; but this is to be expected in view of the number of persons who are new to the business of making cartridges, shrapnel-cases, or copper-rings for shells. All kinds of individuals are visiting the offices of the copper companies, flippantly throwing down a blue-print or two and lightly asking for quotations on anywhere from one million to five million pieces. Many of the copper trade are getting bored because of these experiences. If the seeker after quotations is told that a mill is not properly equipped, he refuses to believe it, or asserts that it really makes no difference; what is needed can be obtained in a hurry. A good part of the purchasing, which runs into millions of pounds, has been negotiated very quietly. A larger foreign business could be done were it not for the difficulty of obtaining ocean freight room, just now a problem with all exports. A number of large inquiries are yet to be satisfied, and the trade thinks that copper will go to 20c. The London market is extremely strong. It was quoted on November 18 at £94 10s. (electrolytic.) Stocks in Great Britain and France are diminishing, as shown by the statistics of November 15. The English supplies on that date were 15,473 tons, against 18,410 tons at the end of October; French stocks were 1645 tons, compared with 1925 tons at the end of October. For some days a strike was on at the refinery of the Nichols Copper Co., Laurel Hill, Long Island, but it has been settled. The company made deliveries out of stocks, and was but little hampered. The base price of sheet-copper was advanced on November 18 to 24.25c. per lb. Exports from November 1 to 19 totaled 12,407 tons.

ZINC

Early this week there was a flood of inquiry in the market, and some large purchases were made for early delivery. Quotations advanced sharply, which served to bring the galvanizers in the market, their appearance sending prices higher. On November 17, spot metal was quoted at 18c., New York, and at 17.75c., St. Louis. The London market was strong at £86 on the 17th. Belief is general that the London market was cornered. It advanced £7 to £85 10s. on the 11th, and the following day went to £87, declined £1 the 15th and on the 18th went to £87 again. The domestic demand for galvanized sheets is very strong, the quotation having gone to 4c. on the 12th. As a result of the United States Steel Products Co. having withdrawn European prices, inquiries are now coming here from neutral countries, even the jobbers having received them. Incidentally, large consumers who usually buy direct from the mills are now trying to buy from jobbers. In the past few days December deliveries of spelter have been quoted at 17c., and January at 16.75c., though quotations vary considerably. Exports have been heavy, amounting to 3989 tons up to November 20.

The quotation for sheet-zinc, carload lots, f.o.b. mill, 8% discount, is 20 cents.

LEAD

As was expected, the A. S. & R. Co., advanced its quotation on November 15, and the new price became 5.25c. per lb., New York. It previously had been 5.15c., or $2 per ton less. The St. Louis quotation is ten points lower. The trade insists that the ordinary domestic demand is not good, and construes the advance to mean that some heavy foreign sales have been made by the leading producer. One report has it that through J. P. Morgan & Co., 15,000 tons was purchased for export delivery in 1916. The London market is not showing strength proportionate to that of the other metals, and the price there is below New York parity. The trade is convinced, however, that a large business is being done with foreign buyers. An even larger movement would take place were it not for the scarcity of freight room already referred to. Independents are well sold up, and are not cutting. Exports from November 1 to 20 totaled 2158 tons.

TIN

The tin market has had a feverish week, but is now quieter and quotations are easier. Early this week the price for spot went close to 45c. It was 37c. on November 10. Late last week the trade could get neither confirmation or denial of the reported closing of the Suez Canal, and buyers rushed into the market to protect themselves. As they did so, quotations went up. At 38 to 41c. between 600 and 700 tons was taken in one day (November 11), while on the following day, when the spot quotation was 44c., about 400 tons was taken. This week the market became quiet, and extremely so when private advices declared that nothing was known on the other side about the intentions of Great Britain with regard to the Canal. Stocks are low in this country and there is every indication that the price of the metal will be fairly well sustained. The quotation on November 19 was 41.62½c. Arrivals up to November 19 amounted to 1100 tons, and there was afloat on that day 4568 tons.

ANTIMONY

Large quantities of antimony have been taken by consumers, and the quotations for Chinese and Japanese grades have advanced to 38.50 and 39.50c. The supply is not large, and now comes a report that Great Britain is making its hand felt in this trade also. It is said that all antimony shipped from the Far East in English bottoms must be consigned to the British Consul at New York, who will release it only under certain conditions

COMPANY REPORTS

BUTTE & SUPERIOR COPPER CO., LTD.

The third quarterly report of this great zinc producer in Montana has been awaited with interest; it contains the following:

	3rd quarter.	2nd quarter.
Ore milled, dry tons	130,210	124,080
Zinc-content, per cent	17.147	17.003
Silver-content, ounces per ton	7.6027	8.067
Zinc concentrate produced, tons	37,396	35,840
Zinc in concentrate, per cent	55.1279	52.706
Total zinc, pounds	41,230,885	37,780,020
Silver in concentrate, ounces per ton	21.9646	22.714
Recovery in concentrate, per cent zinc	92.3322	89.536
Cost of mining	$3.4584	$3.3816
Cost of milling	1.7652	1.8108

The quantity of ore treated was larger than in any previous quarter.

The financial results, compared with those of the previous quarter, were as follows:

	3rd quarter.	2nd quarter.
Net value of zinc concentrate (at mill)	$2,997,128	$2,509,230
Net value of lead concentrate (at mill) and of residue	228,111	230,294
Miscellaneous income	14,715	11,899
Total net value	$3,239,954	$2,751,423
Operating costs	679,625	644,270
Profits	$2,560,329	$2,107,153
Metal inventories and quotations	201,510	.....
	$2,761,839	$2,107,153

The price of zinc on which the earnings are based is 13.6309c., a figure conservatively below the actual prices received on zinc sales made during the quarter, and the value of other products is also conservatively estimated. Spelter sales have been very satisfactory. The company has no unsold metal available for delivery, and a large amount of the estimated production for the remainder of the year has been contracted for sale at prices higher than those prevailing during the third quarter, and all concentrate production for the current year has been contracted for smelting.

The item of $201,510 'metal inventories and quotations' represents excess of actual amounts received from the sale of concentrates and smelter residues above the value at which these products are estimated in monthly statements.

At the end of the quarter, and after payment of dividend at that time, the company had on hand approximately $5,000,000 in quick assets, consisting of cash and products conservatively valued in process of treatment and in transit.

During the quarter the Black Rock shaft was continued to a depth of 1759 ft., the progress in sinking having been 56 ft. A station was cut on the 1700-ft. level, and a skip-pocket made at 1600 ft. Preparations are now being made to sink a new working shaft of greater capacity than the present one, designed for mining at much greater depths than could be economically served with the present small shaft. This new shaft will be situated entirely out of the orebody, and when completed will release large bodies of ore adjacent to the present shaft, which cannot safely be mined while that shaft is in continuous use as a main ore exit.

It will require more than a year's time to complete the new shaft and its equipment; in the meantime the present shaft will only be extended sufficiently to permit of regular production and at the same time facilitate development necessary to maintain liberal opening of ore reserves ahead of extraction. Underground development for the quarter was satisfactory in every way. Extensions of the orebody were disclosed in an easterly direction on all of the principal lower levels where work is now being conducted. No re-calculation of ore reserves was made for the third quarter; but it may be said that the new reserves developed were practically equivalent in quantity to the ore mined.

NATOMAS COMPANY OF CALIFORNIA

The president of this company, Frank B. Anderson, on November 15, issued a report containing the following information:

The Natomas Company of California was organized under the laws of the State of California, on December 24, 1914, to take over all of the properties of Natomas Consolidated of California. This was accomplished through a reorganization plan, with which the security-holders are familiar.

The tested dredging ground at January 1, 1915, contained about 190,000,000 cu. yd. of gold-bearing gravel. Since this estimate was made, additional prospecting on other areas included in the dredging department indicates that considerable additional ground exists, which will increase the net recovery from dredging operations. Twelve boats are operating, and another, Natoma No. 4, is now under re-construction and should be in operation by the first of the coming year. About 2,000,000 cu. yd. per month is being dredged. In 1914 the gross recoveries from these operations amounted to $2,650,579, of which $1,520,946 was net over cost of operation. During the first seven months of 1915 the gross gold recovery was $1,377,159, of which $655,115 was net. During this latter period the boat now under re-construction was not in operation, large expenditures were also necessary for dredge repairs and replacements during this period, all of which were charged to operating expense. The dredges have all been maintained in first-class condition. The figure at which the dredging property is carried as assets on the balance-sheet represents the estimated return during its life, less the cost of recovery and an amount sufficient to cover the amortization of the plant, including dredges.

The company owns and operates two rock-crushing plants, one at Fair Oaks bridge, Sacramento county, and the other at Oroville, Butte county, with a combined capacity of 3000 tons per day. There has been a good demand for this material, and the profits in this department have been satisfactory during the last 18 months, but the business is of such a variable nature that it would not be wise to attempt an estimate of the results to be expected for any period.

The reclaimed lands of the company, approximately 58,380 acres, lie immediately north of Sacramento, and extend for 36 miles along the Sacramento, Feather, and Bear rivers, in what are known as reclamation districts No. 1000 and 1001. When, in the early part of 1914, the re-organization committee took charge of the affairs of Natomas Consolidated, the reclamation work was in an unfinished state, and the lands in consequence were subject to annual flooding, and could be rented only during the dry season, for pasturage. About $1,800,000 had at that time been expended for reclamation work in the two districts, and it was estimated that $1,680,000 would be required to complete it.

As the Natomas company owns 85% of the lands in district 1000, it was necessary for it to undertake the construction work, and take district warrants and bonds in payment therefor in order to insure the completion of the reclamation work. Owing to certain features of the general plan for the reclamation of the two districts, it was necessary to complete the levee systems of both simultaneously, and as a consequence the Natomas company was also called upon to assist in financing the work in district 1001, in which the company owns about 40% of the acreage.

The satisfactory net proceeds from dredging during 1914 permitted the appropriation of sufficient funds to complete this

reclamation work before the close of that year, so that the levees successfully withstood the flood waters of last winter season.

About 35,000 acres of the company's lands in these districts were farmed during 1915 on a crop share rental, and the net returns to the company amounted to approximately $112,000. The drainage system comprises 31 miles of main drainage-canals, 74 miles of lateral ditches, two pumping plants, one containing four 50-in. pumps (now installed) and the other to contain two 38-in. pumps. It is expected that the drainage system will be entirely completed before the heavy rains of this season.

Results from the American River lands and the Natomas Water Co. are quite satisfactory.

Capital assets are worth $19,375,500, including the dredging, rock, water, and land plants; property suspense account, $6,329,500; securities and investments (in reclamation districts), $2,192,490; current assets (including $329,152 cash), $1,482,450; and deferred charges to operating surplus, $17,546, making total assets of $29,397,486. Liabilities include capital stock, $16,035,500; mortgage and bonded debt, $12,715,204; current liabilities, $268,255; reserves, $88,196, and operating surplus at July 31, 1915, $290,331.

MINING DECISIONS

Location and Assessment

The following query has been sent us:

"Mr. Smith located a mining claim on July 10, 1913, and was put on record at the same time. In the same summer that year he does enough work for the assessment, but in 1914 he does no work on the claim, and the work he did in 1913 is not put on record. On January 1, 1915, the claim runs out. On June 6, 1915, Mr. Adams comes along, and Smith offers him a half interest in the claim, and the claim is put on record according to law, they, Smith and Adams, having re-located the claim as partners.

"The point in law requiring explanation is this: Smith located the claim on July 10, 1913, and worked or prospected that summer, but did not record his work. In 1914, he does no work, and lets it run out. In 1915, on June 6, he takes in a partner and re-locates the claim as partners. Smith located claim in July 1913, and let it run out in 1914. He, Smith, re-located the above claim 22 or 23 months after July 10, 1913. Does the failure or neglect of any locator of a mining claim to perform development work of the character, in the manner, and within the time required by the laws of the United States, disqualify such locators from re-locating the ground embraced in the original location or mining claim, or any part thereof, under the mining laws, within three years after the date of his original location, and any attempted re-location thereof by the original locators shall render such location void? What should Adams do to hold his share in claim and have a clean title? Should he, Adams, re-locate the claim in his own name and give half to his partner, or would such be liable to a law-suit? that is, by Adams re-locating claim."

The above query is not as simple as it seems, and it raises a very novel question. Under Section 1426s of the California Civil Code, the failure of the locator of a mining claim to perform his annual assessment work disqualifies him from re-locating the ground at any time within three years from the date of his original location. The re-location of the claim within the three-year period by the original locator and a partner ought not to result in rendering the location void, provided the partner is himself a qualified locator and there is no collusion or fraud in the re-location such as a manifest attempt to evade the statute. Under these circumstances, assuming that the State statute in question is valid, the partner would own the entire claim, since the original locator is prohibited from himself re-locating, and naturally from joining in a re-location. Whether the original locator would have any recourse as a partner, and could compel Adams to later on convey to him any portion of the claim, would depend largely on circumstances. For example, a court of equity might take into consideration the fact that Smith had expended money or labor on the claim, and in this manner between him and Adams, it might be inequitable to allow Adams to retain the entire title. If Adams is a *bona fide* locator, clearly no third person could come in and question the validity of the re-location, for Adams is qualified to locate the entire claim; and if Smith, through the operation of the statute, is disqualified from becoming a co-locator, then the entire claim would belong to Adams, except that he might, as indicated, occupy such a relationship as co-locator to Smith that the latter could eventually compel an equitable settlement. A conveyance by Adams to Smith (after the three-year period had expired) of such an interest in the claim as would make Smith a one-half owner in the claim as a result of the conveyance, ought to straighten the matter out as far as Smith is concerned. The foregoing analysis will give some idea of the nature of the problems involved and is by no means submitted as being conclusive.

Upon giving the matter more careful consideration, however, it seems that the safest way to proceed will be to rely on the original location of July 10, 1913. Smith and Adams can make a mutual conveyance which will recognize the existence of this location and vest them each with a half interest in the mine. This, of course, is on the assumption that no one else has made an adverse location of the property since July 10, 1913. In the absence of any adverse locations, there was no necessity for making the re-location of June 6, 1915, for a mining claim does not, except in Alaska, become invalid and run out merely because the assessment work is not done. If there are no adverse locations, the original locator can perform $100 worth of work at any time and keep the old claim alive. If one proceeds on this theory, he will have to perform $100 worth of work without delay, if this has not already been done this year, and credited to the old location.

Miners' Liens—Receivership on Foreclosure

Held, that Section 8, Chapter 51, Laws of 1909 of South Dakota providing that a receiver of mining property might be appointed upon the mere filing of a suit to foreclose a miners' lien against said property was void, and amounted to a deprivation without due process of law, and an *ex parte* order made in pursuance therewith without notice to the mine-owner should be vacated.

Cessna *v.* Otho Development & Power Co. (South Dakota), 153 Northwestern, 380. June 19, 1915.

Electro-Thermic Smelting of Iron Ores in Sweden. By Alfred Stansfield. No. 344. P. 65. Ill., index. Department of

Mines, Ottawa, Canada, 1915. Sweden is a country of large electric power development, resulting in great strides in smelting by electricity. This is a valuable contribution to the subject, written by a man who personally investigated the industry.

U. S. Bureau of Mines, Washington, D. C.:

Pulmonary Disease Among Miners in the Joplin District, Missouri. And its relation to rock-dust in the mines. A preliminary report. By A. J. Lanza and Edwin Higgins. Technical paper 105. P. 47. Illustrated. Abstracts have appeared in the Press from this publication.

Report of the Selby Smelter Commission. By J. A. Holmes, Edward C. Franklin, and Ralph A. Gould, with accompanying papers by other members of the Bureau staff. Bulletin 98. P. 528. Ill., map, charts, index. This bulletin describes in detail the methods used, some of them new, in determining the contamination of the air and the damage to trees, crops, and live-stock by the smoke and fume from the Selby smelter, in California, and gives the conclusions of the Commission on the methods used by the smelter company to prevent injury. The bulletin is of especial interest to metallurgical companies, municipal or state boards of health, and persons investigating damage by smelter smoke. Owing to the expense involved in the preparation and publication of this bulletin, and the limited printing funds available for the use of the Bureau, it has been necessary to place a price of $1.25 on the work. Orders should not be sent to the Bureau of Mines, but should be addressed to the Superintendent of Documents, Government Printing Office, Washington, D. C.

Department of Mines, Wellington, New Zealand, 1915:

Mines Statement by the Minister of Mines for the year 1914. P. 118. Ill., maps. The mineral output of the Dominion amounted to £3,297,927, an increase of about £100,000.

Imperial Valley and Salton Sink. By H. T. Cory. P. 438. Ill. John J. Newbegin, San Francisco. For sale by the Mining and Scientific Press. Price, $3.50.

The transformation of the Imperial Valley from a worthless desert into a cultivated region with an assessed valuation of many millions is one of the most interesting as well as one of the most romantic episodes in California history. Now that the Imperial Valley irrigation district is established on a reasonably firm financial basis and the other troubles of the valley are well on their way toward solution, it is fitting that a history of the project should be published. The main part of the book is Mr. Cory's paper presented before the American Society of Civil Engineers in January 1913, together with the discussion that followed its presentation. There is also, however, a description of the region at the head of the Gulf of California, by the late William P. Blake, who while connected with the Pacific Railroad surveys in 1853, made the first scientific study of the region. Then follows a summary of various facts regarding the region, abstracted by the author from various scientific monographs, also a description of the watershed of the Colorado river. The reprint of Mr. Cory's paper follows. As most engineers will remember, this paper discussed the shortage of water that induced the California Development Co. to make the cut that it seemed for a time would result in permanently diverting the Colorado river. The paper then describes the various unsuccessful attempts to close the break and the final closing, together with the means taken to prevent a recurrence of the trouble. Most of the men who were connected with the work itself as well as many other prominent engineers, participated in the discussion of the paper. In closing, the author summarizes the events that have taken place since the appearance of the paper.

Commercial Paragraphs

Three additional 10 ft. by 48-in. Hardinge mills have been ordered by the Anaconda Copper Mining Company.

The Connersville Boston type blower, for flotation and other high-pressure service, is described in Bulletin 23 of the Connersville Blower Co., Connersville, Indiana. Some notes are also given on the valveless rotary vacuum-pump.

The Georgia Slide mine at Georgetown, Eldorado county, Cal., has ordered equipment for development including air-compressor, rock-drills and sampling-plant. This property has a big low-grade body of gold ore and promises to be a good-sized proposition. Robert E. Cranston of San Francisco is in general charge of developments. More equipment, such as permanent mill and buildings may follow later.

'Cooling-Ponds for Condensing-Engines' is the title of a paper read by Lee H. Parker, president of the Spray Engineering Co., Boston, Mass., before the National Association of Cotton Manufacturers, at its 99th meeting, New London, Conn., on September 11. Pollution of river water by waste products from manufacturing processes led to the English practice of constructing cooling-ponds for the circulation of hot water from condensers. The water current was diverted by various means. Then natural-draft cooling-towers were developed, the water gradually dropping through a series of shelves or floors. The spray-cooling system next came into use, in which the hot water is forced through nozzles, thus coming in contact with sufficient air to cool it. The spray-nozzles are the most important feature of this system, for which several advantages are claimed over towers of good design.

Robert E. Cranston has been appointed consulting engineer for the design of a new gold dredge to be built for the Chiksan Mining Company, Chiksan, Korea, by the New York Engineering Co. The Chiksan Mining Co. is an American-Japanese enterprise that has been operating lode mines in Korea for some time, this being its first dredging venture; J. R. Geary of Yokohama is president. The dredge will cost approximately $250,000 and will take several months to build. As special features it will have a by-pass for clay (some clay being anticipated in the gravel), and there will be also a special re-soiling arrangement designed by Mr. Cranston. The dredge will have a steel hull 110 ft. long by 50 ft. wide by 10 ft. deep; buckets will be 10½ cu. ft. to dig 25 ft. below the water-line with 15 ft. bank; a revolving screen; it will dig with spuds or headline; a 60-hp. boiler will heat water on the dredge, and in the pond on account of the freezing weather occasionally experienced in Korea; the hull and machinery without electric equipment will weigh 1100 tons.

Two new booklets, Forms 76 and 9201, have been issued by the Ingersoll-Rand Co., 11 Broadway, New York. The former's title is 'Water Lifted by Compressed Air.' It is a treatise on the air-lift and explains this system of pumping. All those interested in adequate water-supply will appreciate this booklet, since it very intelligibly presents facts essential to the analysis of a scheme involving the use of clean water in quantity. The other publication is a 128-page 6 by 9-in. catalogue on Calyx core-drills. The principal function of this drill is the determination of the character, order, thickness, and extent of the materials beneath the earth's surface, by means of cylindrical cores which it extracts. In coal and metal mines, stone quarries, contract work, or for canal or tunnel developments projected, the core-drill is used, and is claimed to take what is otherwise an unknown quantity and converts it into an absolute certainty. By determining the actual conditions in advance, it is a medium to save a large sum in machine equipment, underground workings, etc., that might otherwise be expended only to find a barren property. The booklet is illustrated, gives size and capacities of the different types, and shows the apparatus in operation in various fields.

EDITORIAL

T. A. RICKARD, Editor

SPEAKING of 'horses' in schist, we are reminded of the story told of Clarence King. He had a call to examine a mine in which a 'horse' had spoiled the ore-shoot. He went, and telegraphed saying: "Your mine is a livery-stable."

WE UNDERSTAND that the decision of the District Court of Delaware in the Minerals Separation *v.* Miami lawsuit will be handed down during the current month. The Supreme Court decision on the final appeal of the Butte & Superior is expected in the spring.

PREPAREDNESS will require the consumption of much metal in the manufacture of munitions. The mining industry is an important factor in facilitating such 'preparedness.' Fortunately the United States can supply the various metals required for military or naval construction, all save nickel, and a supply of that is available just across our northern border.

SUPPLEMENTING the note in our last issue, we are able to state that Mrs. Carrie Jane Everson, who patented the essential principle of flotation 29 years ago, died at San Anselmo, California, on November 3, 1914, at the age of 73 years. She left Denver in March 1909 and lived in California during the last five years of her life. Mrs. Everson was not a school-teacher, her brother was not an assayer, and she did not make the discovery while "washing greasy ore-sacks" as has been reported repeatedly.

IN a suit now pending in London over apex-rights in Rhodesia, the novel plea was put forward that the reports made to a mining company by its engineer were not necessarily accepted by the directors as true, "but merely as statements of what is probably happening." Of many Rhodesian reports it may be said, of course, that they reflected improbable developments, but as they were given by the directors to the shareholders in the guise of accurate—even meticulously accurate—information, it comes with poor grace from them now to refuse to allow the reports to be used as evidence in Court.

ONE of the curious consequences of the War is the suggestion to ship the zinc-lead ore of the Bawdwin mines, owned by the Burma Corporation, from the Northern Shan States—where these mines are situated—to Australia. A favorable consideration of the proposal to establish a smelter for this purpose in Australia is assured by the Premier of the Australian Commonwealth. It is estimated that the Bawdwin mines can produce 75,000 tons of lead, 65,000 tons of zinc, and 7,000,000 ounces of silver per annum. Just before the outbreak of hostilities in Europe, the zinc-lead ore, which resembles that of Broken Hill in being an intimate and refractory mixture, was being shipped tentatively to Germany. Since then an effort has been made unsuccessfully to obtain satisfactory reduction facilities in England.

GOVERNMENT aid to mining is not unknown in the older mining regions of the world. It comes usually as a belated recognition of the importance of the industry. We note that the Government of New South Wales has subscribed $200,000 to the fund of $510,000 being raised by means of receiver's certificates for realizing upon the ore and other assets of the Great Cobar copper mine in New South Wales. If the Government had given a friendly hand or lifted a warning finger during the earlier days, when labor shortage and reckless promotion joined in bringing the enterprise to a pitiful collapse, it would have been better for the shareholders and the State.

A DIFFICULT shaft-sinking problem is always interesting. The description—appearing in this issue—of sinking through broken rock against high water-pressure was written by the assistant-superintendent for the Cleveland-Cliffs Iron Co. in the Gwinn district. Accounts of sinking through quicksand by using the caisson method, so that no pumping is done, the sand and water being held back by compressed air, have appeared in previous numbers of the MINING AND SCIENTIFIC PRESS. The article describes a method employed by the mining company to continue the sinking after the shaft had been sealed to bedrock by the Foundation Co. As no pumping had been done in the 100 ft. of sinking to bedrock, it is obvious that the thick overburden must have contained a tremendous body of water, it being remembered that the soil in northern Michigan is Glacial drift with a tendency to hold moisture. It may be asked why ordinary methods of sinking and pumping were not adopted, merely lining the shaft through the broken rock with a tight concrete wall; but how could the concrete be placed in position against a flood of water that would rush from the rock in torrents? A consideration of the problem shows the advantage of the method used.

FROM LONDON we hear that the Tomboy Gold Mines, operating at Telluride, Colorado, is well pleased with its recent purchase of the Sidney-White Cloud group of claims, situated north of the Bushwhacker claims and covering 4000 feet on the Montana vein. The price was

$75,000, which is small, having regard to the enlargement of the company's resources ensured by the transaction. This is the third or fourth time that the life of the Tomboy property has been usefully prolonged. When we remember what a disappointment the original Tomboy mine proved itself, and how the fortunes of the company were retrieved by the purchase of the Argentine, and how the Argentine was replaced by adjoining property when it also was exhausted, we conclude that the shareholders of the Tomboy have much reason to be grateful to their directors, particularly Messrs. R. T. Bayliss and J. H. M. Shaw, and to their successive mine managers, the two Herron brothers. Evidently the directors of the Tomboy regard themselves as trustees for the shareholders and not as privileged speculators on their own account. We hope the example will prove contagious in London.

SILVER, much to the delight of the miner, has risen from the low level of 46¾ cents on August 25 to 56½ cents per ounce during the past week. This has caused particular rejoicing not only at Tonopah and Cobalt, but also in Colorado, the Coeur d'Alene, and throughout the West. The reason for this rise is the withdrawal of gold from circulation, owing to the War, and the greater need for silver in metal currency, to sweeten fiat money. The United States produces one quarter to one third of the world's annual output of silver, but North America as a whole ordinarily produces nearly three-quarters of the grand total. The European governments are keeping a tight hold on gold. Meanwhile India, which is a veritable maw for silver, absorbing 55% of the world's annual output, continues to call for both silver and gold. The natives of Hindostan learned many years ago to hoard gold, rather than silver, for the Government levies an import-tax on silver, while admitting gold free. During the past three years 30% of the world's gold production has been going to India, while elsewhere the people usually described as more civilized have been learning to lay aside wealth in paper credits, doing business in notes, debentures, and bonds. Recently the demand for silver from China has improved and the renewal of trade prosperity in the United States has revived the consumption of the metal in jewelry—a sure index of better times.

AS our readers are aware the word 'mine' is derived from a Roman military term, since mining and sapping under fortifications played a greater part in the ancient world than the digging for metals. In these days of supposedly advanced civilization the term has resumed much of its former meaning, for 'mines' imperil navigation no less than they endanger the movement of troops on land. Hence it is not surprising that the mining engineer should be called from his peaceful and beneficent occupation of excavating ore underground to the destructive operations of the battlefield, where he is now engaged in digging tunnels to undermine the enemy's trenches or in counter-sapping similar efforts of the opposite side. The mining engineers in the Allied army are doing their work well, as becomes professional men. We note that Sir John French has 600 mining engineers among his forces. In a recent dispatch to Lord Kitchener he says: "I desire to call your lordship's attention to the splendid work carried out by tunnelling companies. These companies, officered largely by mining engineers and manned by professional miners, have devoted themselves whole-heartedly to the dangerous work of offensive and defensive mining, a task ever accompanied by great and unseen dangers." We do not doubt that the engineers graduated from Freiberg and Clausthal are doing their best for the other side, and we only regret that members of a world-wide profession should have to kill each other in order to prove which school of political thought is the better.

Drill-Steel

The captains of modern industry know the economy of using the best tools. Of the total cost of mining, fully 65% is represented on the pay-roll, that is, by wages paid to workmen. Time is money; the saving of time through the use of the most efficient tools is axiomatic. The miner is an instrument of industry, deputed to perform a given task; therefore it behooves the employer to render that instrument as effective as possible. One way is to make him physically fit and mentally comfortable. Hence the welfare movement. Another way is to supply him with the best tools that money can buy. The point of mining is the drill. That implement, driven home by air, steam, or muscle, does the work whereby the metal-bearing rock is broken so that it can be moved from its place underground to another place where it can be subjected to the successive reductions and treatments that finally separate the valuable metal from the valueless gangue. To make a drill and a drill-bit that will stand the strain of rapid concussion without displaying either shortness of temper or 'fatigue' is the aim of the mining economist. Of late, the tendency has been to focus attention on the drill as a machine, while overlooking the improvement of the steel in the bit that constitutes the business end of the mechanism. This fact was emphasized lately in an excellent article by Mr. L. O. Kellogg in the *Engineering Magazine*.

One of the many advances in drilling during recent years has been effected by the introduction of hollow steel, whereby water is admitted in such a way as to allay the deleterious dust and remove the rock-chippings. With the use of hollow steel has come also the rapid introduction of the hammer type of drilling machine, in preference to the older type that derives its impulse directly from a piston. The hollow steel of the hammer-drill is subject to excessive strain by reason of the high speed, which in some cases reaches 1500 blows per minute. Only the best quality of steel is fit for this service. Moreover, the critical factor in the business of supplying drill-steel to mines is not the first cost but the unit cost—the cost per ton of ore mined. In this cost the expense of the steel is only one item. The expense of sharpening, the loss of time in changing bits, and in taking them to

the blacksmith are among the other items to be noted.

Competition between domestic and foreign steel is another interesting phase of the problem. The salesman will tell you that Swedish steel is made from a purer and more homogeneous ore than any to be obtained in the United States, and he will assert that it is manufactured by workmen more skillful and more experienced. The American salesman will belittle such claims, insisting that his firm has beaten the Swedes at their own game by methods evolved in a research laboratory, and that, although the Swedish steel happens to be cheaper in first cost, this is due to cheap labor, rather than any superiority of manufacture. The fact is that Sweden does possess a supply of ore peculiarly free from phosphorus and sulphur. No coking-coal exists in their country, so that smelting by means both of charcoal and of electricity has been developed. The abundant water-powers of Scandinavia have stimulated the use of the electric furnace. This method of making high-grade steel is superior to processes using coke, which tends to introduce its sulphur into the iron from which the steel is made. At the famous electric plant at Trollhättan, the ore mixture contains 63% iron, 0.01% sulphur, and 0.015% phosphorus. A much larger electric furnace has been started recently at Domnarfvet, where 10,000 horse-power is consumed as compared with the 2500-hp. furnace at Trollhättan. It is claimed that the average iron ore from the Swedish midlands runs between 0.005 and 0.02% in phosphorus and between 0.005 and 0.05% in sulphur, and that in the concentration by the Gröndal process ore containing as much as 1% phosphorus is refined to a concentrate much of which contains less than 0.01% of either phosphorus or sulphur. The greater part of Swedish soft, or mild, steel is so free from these two deleterious elements that large round bars when cold can be tied into knots without sign of fracture. The iron and steel output of Sweden is not large; the aim is said to be the production of quality and high-grade variety rather than tonnage. Labor in Scandinavia is relatively docile and cheap, and the easy access to tide-water facilitates maritime transport. So much for the Swedish steel.

Americans have awakened to the opportunities afforded by the market for high-quality tool-steels, which are being manufactured at a rapidly increasing rate. Most of the output is for domestic consumption. One enterprising company that formerly imported Swedish steel is now making its own material in a New Jersey factory. Americans have also adopted the electric furnace, and when our people once catch the idea of a process—for example, flotation—they soon ascertain the essentials in the method of the other fellow and add improvements of their own that accomplish astonishing industrial results. The great advantage of the electric furnace is the facility for perfect control of the heat, so that just the proper temperature for just the right time can be maintained, as against the older methods with their uncertain conditions. The electric furnace as a factor in steel-making has been so recently perfected that it may be doubted whether the Swedes, even with their long experience in iron-working, have any substantial advantage over our more progressive manufacturers. As to the purity of ore, this country possesses several iron deposits that are well adapted for the purpose.

There is also the question of alloys. Hitherto, drill-steel has been little more than a high-carbon product, specially treated, the carbon content usually being from 0.70 to 1%. Alloy-steel has been so expensive and so little appreciated that its use in drills has made slight progress. Furthermore, the average mine-blacksmith, whose task it is to sharpen the drills, has usually lacked both the time and equipment for treating special brands of steel properly. Nowadays, however, progressive mining companies are installing mechanical sharpeners, which not only achieve a substantial saving in the cost of sharpening, but produce a more uniform bit. Of course, while the War lasts, the price of some alloys will be prohibitive. Thus, tool-steel containing 18% tungsten is selling at $2.50 to $3 per pound, while molybdenum alloys are equally high-priced. On the other hand, search is constantly being made for such alloy-components, and it is reasonable to expect that before long the United States will not have to depend upon foreign sources of supply. At present a great diversity of opinion is manifest as to the actual functions of the alloy components, such as chromium, manganese, tungsten, and others. One manufacturer claims that he can adapt a high-carbon steel to hard-rock drilling by merely adding manganese, to lessen brittleness and give the toughness that has caused low-carbon steel to be required for such work. There is no doubt that the War has afforded the manufacturer an excellent opportunity to show what he can do for the miner in this respect.

Electro-Statics in Flotation

In this issue we publish the text of a paper read by Mr. J. M. Callow before the Salt Lake section of the American Institute of Mining Engineers on October 4; the delay in publication arises from the fact that the paper was not 'released' until it had been printed for the December bulletin of the Institute, at New York. The detailed description and drawings of the pneumatic cell, designed by Mr. Callow himself, will be welcomed by those interested in flotation—and who among millmen and metallurgists is not? The flow-sheets outlining the various schemes of treatment adopted by the National Copper, Inspiration, Arizona Copper, and Daly-Judge companies will prove suggestive. But the most interesting portion of the paper is the discussion of the principles underlying the obscure phenomena of flotation, more particularly the electro-static characteristics of the ores that are most amenable to the process. That floatable minerals exhibit evidence of being charged electro-positively, while the non-floatable gangues show corresponding signs of negative electrification, is a fact of fundamental importance, indicating a promising line of research. It appears likely that flotation is due in part,

at least, to the difference of polarity in the charges on particles of ore and on the bubbles that convoy them. The contact films both of oil and of air having been proved to be negative, it is easy to understand why the positively-charged metallic sulphides should adhere to either of them. This development of theory is a direct result of the study of colloids. As Mr. O. C. Ralston states, it simply became a question whether the effect of electrolytes on colloids could be duplicated to a measurable degree on relatively coarse suspensions of ores such as are treatable by flotation. It has been suggested that the friction engendered during the agitation of the pulp served to generate the electric charges, but colloid chemistry indicates that such charges are created whenever two substances of unlike dielectric constants are brought into contact. In the article by Mr. Thomas M. Bains, Jr., appearing in our last issue, this phase of the subject was discussed in an informative manner. Not only friction, but differences of temperature, cause electrification. That may be one reason why the increased revolutions of an agitator are favorable to froth-concentration in the flotation-cell. The relatively high electric conductivity of the floatable minerals is also suggestive: so is the effect of adding acid. It is worthy of note that the electric explanation of flotation has been taught in the Case School of Applied Science, by Mr. Bains and his chief, Mr. Charles H. Fulton, professor of metallurgy, for fully a year. Researches along this new avenue of scientific enlightenment are being made by the U. S. Bureau of Mines, to the Salt Lake branch of which the industry is already under great obligation for illuminating information.

Individualism and Co-operation

It was pointed out by Mr. L. D. Ricketts in his recent address at the Exposition that the tendency in the United States during the extraordinary industrial development of late years has been toward the limitation of the individual and the concurrent utilization of the power of organization. Mr. Ricketts said: "To accomplish results the individual has had to recognize the necessity for the association of a great variety of talent exercised by a large number of men into a working organization of ability, courage, and spirit." This statement embodies the very essence of modern American business; namely, the willingness to surrender some measure of individuality in order to attain the efficiency required for success in commercial competition with the remainder of the world. Somewhat the same idea is conveyed in President Wilson's popular little book, 'When a Man Comes to Himself.' Mr. Wilson states that the old idea of a man having to live apart from the world in order to obtain the fullest expression of his power has now been superseded by recognition of the fact that a man in constant contact with associates is aided by suggestions, hints, and mental stimuli, combining to furnish him with incentive and opportunity to work effectively. The reason that Americans, who pride themselves particularly on the achievement of liberty, have submitted to the routine and discipline of organization in industry is that they appreciate the superior efficiency of team-work as compared with striving at cross-purposes. Thus has come 'big business,' and the present remarkable exploitation on a huge scale of those low-grade resources that could not be profitably operated in a small way. Americans are notable organizers, promoters, and advocates of the 'work together' idea—at least, in business. Industrial wonders have been accomplished by utilization of this power of organization.

Danger comes from believing that organization is everything: that individual initiative and spontaneity are to be disregarded. Bureaucrats, who delight in corporation politics and petty officiousness, are an example of organization run to seed. Occasionally expression is given to the distorted belief that an organization for this or that can do everything; which it cannot. An organization to make Chicago the art centre of the world, instead of Paris, would fail because art is not manufactured like breakfast-food or soap; individual talent is necessary, as also the state of mind growing out of many generations of belief in art for its own sake. Likewise an organization formed for the purpose of inventing an improved rock-drill or concentrator might fail miserably, while a clear-thinking young miner or millman, of whom no one had ever heard, might succeed in producing exactly the design sought. The point is that a sense of fitness should govern; and that brains, understanding, and genius—erratic and individual as it usually is—should be given encouragement. It is likely, if the great inventors and discoverers of history had been compelled to work under the handicap of particularly overbearing discipline, that they would have been only second-rate mechanics or clerks. A company that loses sight of the necessity for giving scope to individual spontaneity and independent thinking, while devoting all its energy and attention to organization, will soon come to grief. Not infrequently we see capable men, having been discharged or overlooked by one company, going into business for themselves or some one else, and promptly take away trade from the organization that was too dull-witted to recognize their ability.

The reason why a corporation should encourage individuality and thereby loyalty in its members, giving scope to personal ability whenever possible, is because, as pointed out in a publication of the W. S. Tyler Company of Cleveland, "in the final analysis every organization consists of but one man." Frequently at a mine the responsibility of the organization rests upon the hoistman in the engine-room, as when, for instance, he is lowering the directors or management down the shaft. The critical point in every important negotiation—the deciding element that makes the little difference between failure and success—is the influence and personality of one man. It may be, and frequently is, a different man on different occasions, in the same corporation, but the human note counts and is an unquestionable factor in every final analysis. It always will be.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Law and Patents

The Editor:

Sir—Your editorial discussion of this subject in your issue of November 6, appears to be somewhat superficial, and your conclusion that "the patent law is an excavated anachronism" seems to be without sufficient basis. The American patent law, on the whole is good, but that it might be improved, no one will deny.

Your statements, in the article referred to, or their equivalents, have so frequently appeared in the technical press, that I cannot resist challenging them every time I see them. I will, however, consider only three points in your discussion.

First; you say: "Manifestly the Government should not grant the privilege (a patent) without thorough investigation." Are your readers to understand from this, that before a patent is granted, you would put every inventor to expensive litigation? If not, what is a thorough investigation? You mention publicity; but it is an old saying that "What is everybody's business is nobody's business." Who, for example, if your suggestion for publicity were adopted, would have presented the evidence for the public and prior inventors at the time patent No. 835,120 was filed? Remember, at that time there was very little interest in flotation matters, and its possibilities were not realized. Then, if no one had adequately defended the public and prior inventors, the patent referred to would have been granted, as it has been granted under present conditions. Then, are we to understand, if the patent had been granted under your suggestions, that the public and prior inventors should be deprived of all that had been disclosed in the prior art because the public was not adequately defended?

There would be no end of injustice in such a case, both to the public and prior inventors. The latter would be systematically robbed under the guise of legality and litigation, and there would be no redress, once a patent is granted. Manifestly, the only investigation which would be applicable under your suggestion would be litigation, for that is the only way evidence could be adequately presented. Would you force every applicant for a patent into such litigation, both in obtaining a patent, and later, in repeatedly defending it against subsequent applications? Is not the present scheme infinitely better? Under the present system, if there is any reasonable doubt in the mind of the examiner as to the issuing of a patent, the applicant is given the benefit of the doubt, and he can then defend his position in the courts if occasion requires, and, after all, the courts should be the final arbiters in patent cases as in all other cases. Justice is not always made easy, and in the courts new evidence may affect past decisions. Let us bear in mind, that even with all the evidence presented in the flotation litigation, at an expense of many thousand dollars, there is no unanimity of opinion; one court decided in favor of the plaintiffs, and one for the defendants. How, then, would your scheme help matters? The examiner of patents is not to blame for being in doubt, when the courts and all the experts, both technical and legal, with all the present evidence, find difficulty in arriving at a just decision. All your scheme would do, would be to compel every applicant to litigate, and no patentee would at any time be safe.

Second; "Next, it (the Government) should assume the duty of specifying the proper royalty to be collected by the patentee, modifying the impost from time to time according to circumstances and preventing an excessive imposition." This, of course, is the socialistic solution of the difficulty, and no fault can be found with it. The Government should, perhaps, also adjust the various conflicting interests without expensive litigation. Nothing is so new but that it embodies something that is old, and nothing is so old but that it may embody something new. This is clearly the case in the flotation situation. But, let me add with extreme emphasis, if such a socialistic supervision of patent privileges is advisable, it would follow that all products from patented apparatus or processes should be similarly regulated by the Government. Surely you would not be so uncharitable as to advocate the Government regulation of patent royalties, and leave the patentee and the public to the tender mercies of private regulation of the products produced under Government regulation of patents. Let us try and be fair.

Third; "Many patentees—including some of those privileged to use certain phases of flotation—take care to give as little information as possible. * * * This failure to give explicit information marks an effort by the patentee to protect himself in default of protection from the Government." I doubt this explanation: It will probably not apply once in a thousand times. The true explanation is that the patentee himself never realizes the scope of his invention and the best method of carrying it out, at the time the application for patent is filed, and the conditions are such that he cannot realize its scope. An invention, at the time of filing application for patent, is not a finished product: it is merely a beginning. In mining parlance, it would be termed a

prospect. An inventor, as a rule, knows no more of the value and scope of his invention, than a prospector does about a newly located mining claim. The two cases are parallel. As either the prospect or invention is developed, its value becomes more fixed; if it is not promising it is abandoned; if promising, it is developed as far as the outlook is encouraging. Either prospector or inventor may strike it rich; either may go broke. The work and expense of a patentee, in developing his invention, is just as great and just as real as the work and expense in developing a prospect. But, through it all, the prospector does not wait to develop his claim into a mine before he files his location certificate and gets possession; neither does an inventor. The prospector's title is absolute if properly filed; an inventor's rights cannot be so well defined, and it is for this reason, as well as others, that courts have rightly given the broadest interpretation to pioneer patents. So, let us not criticize patentees, or the patent law, for something which in the very nature of things cannot be remedied. The inventor who would wait until he can clearly define the scope of his invention and the best method of carrying it out before filing a patent application, would be a fit subject for the insane asylum. It is for this reason, also, that publicity of patent-applications would amount to positive confiscation and robbery. Instead of greater publicity, more secreey would be the inevitable result. Every inventor's honest efforts should be kept secret until he, himself, desires publicity. If patent-application were given publicity, applications would be delayed in filing, and in case of a contest to determine priority, the result would be that the evidence would be obscure and intangible, as compared with the definite filing-records under the present system. Secrecy, necessarily, goes with the development of an invention.

W. E. Greenawalt.

Denver, November 13.

Mining Accidents

The Editor:

Sir—I am a miner of many years of underground experience, in the various sections of the metal-mining countries of the West. The questions of health and accidents in your pages have prompted me to make a few statements. Some writers in your publication have gone so far as to make no allowance or distinction, but go ahead and stigmatize miners in general as a reckless, careless, and untrustworthy lot. The writer would enjoy having such a man as Harry L. Day and his ilk in some of the gas-polluted holes performing a task with the aid of a companion who could not speak the language of the country; or to see him forced to climb broken ladders with pails of water and blasting material, being furnished neither means nor privilege of looking after safety without imperilling the privilege of laboring. Another thing I would like to see is a mining-magazine editor who is brave enough to collect some statistics on lung diseases caused from air-pollution by gas and dust; to describe the various poisons in the different ores when they are floated in the air, and to explain the function of the cilia of the lung and the effect on the aforesaid organism by the various forms of mineral-dust.

M. Smith.

Bisbee, Arizona, November 20.

[Our correspondent distorts the reference made to the cause of mine accidents; we did say that we had found miners to be "reckless," but we did not say that they were an "untrustworthy, etc.," lot. Mr. Smith will find an article on pulmonary disease among the miners of the Joplin district in our issue of November 27.—Editor.]

Who Owns a Report?

The Editor:

Sir—I note with much interest the editorial discussion on 'Who Owns a Report?' in your issue of October 30.

In dealings with clients I make it a practice not to use the information obtained from earlier examinations for the benefit of new clients, without first ascertaining whether or not my earlier clients are still interested in the particular property. If they are so interested I decline to report without their permission, but if they are no longer interested, then I feel free to use the information at hand.

In but one instance out of a large number of cases have I found clients at all inclined to a dog-in-the-manger attitude. In that instance the man who desired my services took the attitude that my report was his property, that I had no right to report upon the property for others, and that if anyone else desired a report upon the property he would sell the information to them, but I could not do so. Needless to say, I declined to be bound by such a procedure and flatly refused to undertake work upon such a basis.

I feel that knowledge gained in an examination is mine, and that only the particular report belongs to the client who secures it.

One must, to my mind, be guided by a sense of fairness and justice. If an engineer frankly asks his clients whether or not they object to his reporting on the same property for others, he will find in most instances a liberal attitude, and secure a free hand to report for others if the interests do not interfere.

The average business man does not want interference with his business, but I find that he is broad-gauged enough not to feel that he buys a man body and soul when he pays for a report.

Dorsey Hager.

Tulsa, Oklahoma, November 4.

Manganese ore is being imported from Brazil into the United States in increasing amount. During the month of August over 50,000 tons was brought in. The United States imported 283,294 gross tons in 1914, which was less than in 1913 and 1912, and of which India contributed 103,583, Russia 52,681, and Brazil 113,294 tons.

Notes on Flotation

By J. M. CALLOW

*Historical Sketch. The selective action of oil for lustrous minerals was first disclosed by Haynes in 1860. In 1885, Carrie Everson elaborated this idea and also disclosed the fact that acid increased the so-called selective action. Her patent called for oils, either animal, vegetal, or mineral, and also an acid or salt. The process was tried on a practical scale both at Baker City and Leadville in 1889; it failed, first, because, as has since been shown, of the unsuitability of the ore to flotation; second, because her invention was too far in advance of the times. Then followed the Elmore brothers, first with their bulk-oil processes and later with their vacuum scheme. The basic principles of oil-flotation were undoubtedly covered by the above inventors and the work that has been done since their time has been merely a building up on ground-work laid down by them. Different kinds of oil, different quantities of oil, and all the varying degrees of agitation were all exemplified and practised by them in one phase or another; the developments that have since been made are but elaborations of the fundamental principles laid down by Haynes, Everson, and the Elmore brothers.

In 1902 we saw the development of the Potter or Delprat process in Australia. In this no oil was used, but

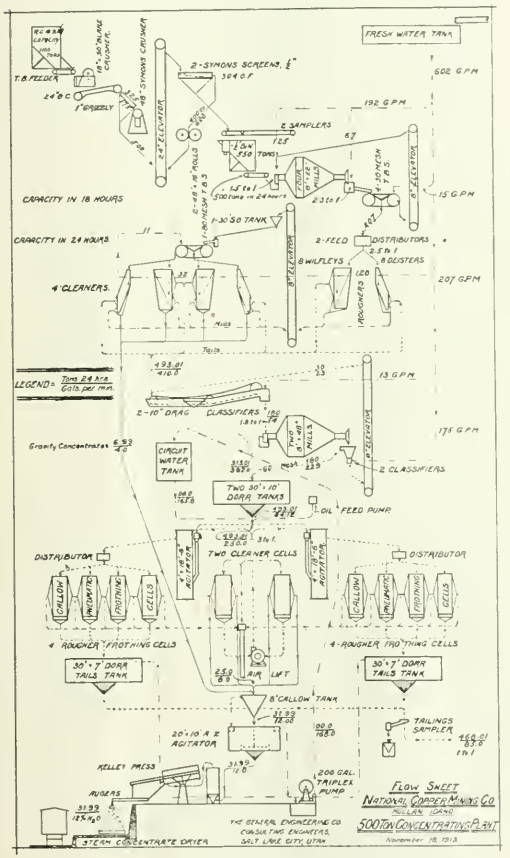

Fig. 1.

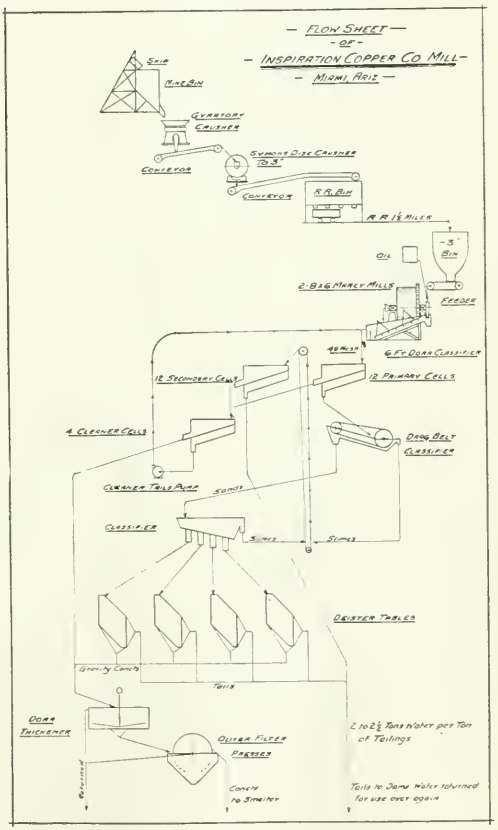

Fig. 2.

*A paper originally presented at the annual meeting of the Utah section of the American Institute of Mining Engineers, at Salt Lake City, on October 4, 1915. To be read at the New York meeting in February.

the mineral was raised by the generation of gas, brought about by the introduction of acid in the pulp so that the mineral appeared on the surface of the separatory vessel in the form of a scum or froth buoyed by minute gas bubbles attached to them, and thus first gave the suggestion of gaseous flotation. In 1902, also, Froment, an Italian, was granted a patent in which he combined violent agitation with oil and gaseous flotation, the gas being generated within the pulp, in much the same way as in the Potter-Delprat process. In the same year, Cattermole came out with a unique scheme. He first emulsified his pulp with a small quantity of oil by violent agitation and afterward submitted it to a slow stirring action in a second machine, by which he granulated or coagulated the minerals that had been oiled into nodules, which he afterward separated from the pulp by gravity. The defect of this process was that only part of the mineral was granulated, the rest of it appearing on the surface of the pulp as a scum or froth, and so was lost in the tailing. This defect of the Cattermole process suggested the fundamental idea of the process afterward described by Sulman, Picard, and Ballot in their patents, in which, instead of granulating part of the mineral, they floated all of it. This patent forms the basis of all the Minerals Separation operations. It was first exploited in Australia and in a short time replaced all other flotation processes in that country.

In 1904, MacQuisten brought out his tube process, a very ingenious scheme which gave excellent results on the sandy portion of the feed, but was inoperative when slime was present. This was a strictly surface-tension scheme, and its inability to handle slime was a serious limitation.

In 1912, Hyde introduced a modification of the Minerals Separation process into the mill of the Butte & Superior company, at Butte, Montana. This differed from the regular practice in that it introduced a double treatment, first 'roughing' and then 'cleaning' the concentrate.

Pneumatic Flotation. Early in 1909, I did a great deal of work with the MacQuisten flotation process and in the installation of the tube-plant of the Morning mill at Mullan, Idaho. This work was followed by a large amount of experimenting on the different kinds of existing flotation processes, the outcome of which was the development of the pneumatic method.

The first application of pneumatic flotation for the treatment of ore was made by me at the mill of the National Copper Co. at Mullan. This plant was designed and built by me and was a success in every way from the very start. Construction was started on August 14, 1913, and the plant went into successful operation about April 10, 1914. The flow-sheet is given in Fig. 1.

Since that date, the method has been adopted by nearly all the other mills in the Coeur d'Alene treating lead and lead-zinc ores, notably the Gold Hunter, Morning, Hercules, Bunker Hill & Sullivan, Caledonia, Last Chance, Hecla, Standard, etc., a total of about 50 cells in all, treating from 1500 to 2000 tons of slime and fine sand per day. The same method also has since been adopted by the Inspiration, Arizona, Anaconda, Magma, and other copper companies, and by the Silver King, Daly-Judge, Duquesne, and El Rayo mining companies, on lead, zinc, and other ores, making a total of some 680 cells in operation or in the course of erection, having a combined capacity of 25,000 to 28,000 tons per day.

The flow-sheets of the Inspiration and the Arizona Copper plants are given in Fig. 2 and 3. The Daly-Judge flow-sheet, in Fig. 4, is an interesting example of the recoveries possible on zinc-lead, fine sand, and slime.

The accompanying diagram, Fig. 5, illustrates the various elements composing the Callow method.

A is a mixer operated by compressed air for the purpose of mixing and emulsifying the oil, the air, and the water, the same type of apparatus being in common use in cyanide work. In cases where the oil or frothing agent can be fed into the crushing machine or tube-mill, this mixer, or Pachuca tank, can be eliminated, so that the oil is fed direct into the mill and thence into the separatory cell.

It has been proved conclusively that agitation *per se* is not necessary to successful flotation by the pneumatic method. In one of the plants a Pachuca mixer for each four roughing-cells was installed. This received the thickened feed from a Dorr tank, which feed was elevated by a belt-and-bucket elevator. The oil was fed into the boot of the elevator and the mixing there served all purposes, since the results without the Pachucas were found to be just as good as with them. Therefore the use of them in this plant has been abandoned.

B is the initial or roughing separatory cell. It consists of a tank about 9 ft. long over all and 24 in. wide, with a bottom inclined at from 3 to 4 inches of fall per foot; it is 20 in. at the shallow end and 45 in. deep at the deepest end. It may be built of either steel or wood, preferably wood.

Figure 6 shows the cell in detail. The bottom of the tank consists of a porous medium made of four thicknesses of loosely woven canvas-twill, properly supported by a backing of perforated metal to prevent bulging when under air-pressure. Through this porous medium compressed air is forced by the blower *E*. Porous brick or any other ceramic material may be used to ensure the necessary fine subdivision of the air. Some of these have been tried, but for practical and mechanical reasons the loosely woven canvas-twill seems to serve all purposes better than anything else, and has been adopted as the standard porous-bottom construction.

The space underneath this porous medium or bottom is subdivided into eight compartments, each connected by an individual pipe and valve with the main air-pipe *F*. By this means the air-pressure to each compartment can be regulated (by throttling the valve) to correspond with the varying hydraulic head within the tank, so as to discharge a uniform amount of air throughout the length of the bottom and maintain a uniform aeration of the contents. A pressure of from 4 to 5 lb. is generally used and each square foot of porous medium requires from 8 to 10 cubic feet of free air per minute.

Each longitudinal edge of the tank is provided with a lip and an overflow gutter for the reception of the froth to be discharged. The lower end of the tank is furnished with a spigot-discharge fitted with a plug-valve, operated by a float, for the purpose of maintaining a uniform water-level within the tank, thus in turn securing a uniform and constant discharge of froth under all the varying conditions of feed incident to practical milling operations. The water-level, may, of course, be varied; but it is usually maintained at about 10 to 12 inches below

Parallel or Series. The machine may be run either in parallel or in series without any sacrifice in capacity for a given number of cells. Recent experience goes to show that, on some ores at least, the series treatment gives a slightly better tailing; on others it does not. It is unnecessary to extend this arrangement of cells beyond two cells in series. In a heavily mineralized ore this arrangement is decidedly advantageous and in such a case the rougher-concentrate might be of high enough

the level of the overflow-lips. The tailing is discharged through the spigot and the frothy concentrate is conveyed by means of the side-gutters to the pump *D*-1, thence to the cleaner-separatory cells marked *C*. This cleaner-cell is a machine of the same construction as the rougher; in operation, however, it is usually run with a lower air-pressure; the tailing from the cleaner is pumped by *D*-2 back to the original feed, and thus a closed circuit is maintained on this portion of the feed. The concentrate from the cleaner is the shipping or finished product. Pump *D*-1 can well be eliminated by setting the cleaner at a lower elevation and conveying the rougher-froth to it by gravity. Usually one cleaner serves four roughers.

grade to omit the re-cleaning operation. The froth from the second cell in the series might be returned into the original feed in the same way that the tailing is returned from the cleaner when practising a roughing and cleaning operation. A number of such combinations is possible. At the Inspiration, the original feed goes to 12 primary roughers, the tailings from which are classified into sand and slime, the sand going to tables and the slime being returned to 12 secondary roughers. The concentrates from both the primary and secondary roughers go to four cleaners, and the cleaner-tailing back into circuit.

Froth Formation. The froth is generated as the re-

sult of injecting the finely divided air into the bottom of the already emulsified pulp; it continues to form and to overflow so long as it is furnished with pulp of the proper consistency, properly mixed with the right quantity and kind of oil or frothing agent. Measured from the water-level within the tank, the froth produced may be from 14 to 16 inches in depth or thickness, and according to the character of ore, kind and quantity of oil introduced, will be more or less voluminous, coarse or fine grained, dry or watery—all of these conditions being adjusted by the regulation of the kind or quantity of oil and the quantity of air injected.

In the case of some ores, rich in sulphides, when a comparatively low-grade concentrate will suffice, the 'cleaner' may not be necessary, but on low-grade ores having a high ratio of concentration and demanding a concentrate of maximum purity, a cleaner is desirable.

Pulp-Density. The pulp to be treated may be of varying density, from 2½:1 water and ore, up to 5 or 6:1; for a mixture of sand and slime the former ratio is preferable, but for a pure slime mixture (–200 mesh) the larger proportion of water is allowable. The particular density is not a matter of so much importance as that the supply of pulp be uniform in density, since each variation in the density of the pulp requires a re-adjustment of the oil-supply, the quantity of oil increasing in proportion to the increased volume of pulp, independent of its solid content.

Capacities. A normal capacity per standard roughing-cell is 50 tons per 24 hours. This, of course, will vary with the nature of the ore. In one plant that employs gravitation previous to flotation the fine sand and slime only are treated at the rate of 50 tons per rougher. The Inspiration Copper Co. uses flotation as the prime process, and its 800 tons per section is treated by 24 roughing-cells and 4 cleaners. In this case the cells are run in series, the primary cells treating the original feed and the secondary cells re-treating only the slime from the primary tailing after the sand has been removed. This gives an average of 33.3 tons per roughing-cell. The Arizona Copper Co.'s plant will treat the slime and re-crushed sand from previous gravity-treatment; out of an original tonnage of 4000 there will be about 3600 tons of flotation feed. This will be handled on 63 roughers run in parallel, and 18 cleaners, or an average of approximately 57 tons per roughing-cell, or 45 tons per cell for roughing and cleaning.

Some tests have shown little difference in recovery, whether running 45 tons to the cell or 65; but the recoveries commence to decline as soon as the feed exceeds 75 tons. In the Coeur d'Alene, on zinc-lead ore, 35 tons per cell is an average capacity.

Oils. The oils used may be broadly divided into 'frothers' and 'collectors.' The pine-oils are good frothers; coal-tar and its various subdivisions are good collectors. On some ores crude pine-tar will in itself combine both the properties of frothing and collecting. On others, this may have to be enriched by the addition of some one of its more volatile constituents, such as refined pine-oil, turpentine, or wood-creosote.

Generally speaking, the coal-tar products are poor frothers; to get a sufficient volume of froth to insure a high recovery, it is often necessary to add refined or crude pine-oil, creosote, etc. At the Inspiration, for instance, the mixture is 80% crude coal-tar, 20% coal-tar creosote; at another plant on similar ore 45% El Paso coal-tar, 40% coal-tar creosote, 10% cresol, and 5% pine-oil. At the Daly-Judge we used 40% crude coal-tar, 40% creosote, 20% pine-oil. In the Coeur d'Alene on zinc ore we used straight wood-creosote; on the National Copper ore plain turpentine will work, but pine-oil is better. At the Inspiration we used from 1½ to 2 pounds of the mixture per ton of ore; at the Daly-Judge, 1 to 1½ lb.; and at the National 0.3 lb. oil is sufficient. In the experimental work at another plant the consumption of oil was approximately one pound of mixture per ton, but since the entire plant has been in operation and the circuit-water is reclaimed and used over again, the oil consumption has dropped from 1 to 0.35 lb. The proper kind or kinds of oil and the quantity requisite can only be determined at present by tentative experiment; so far no scientific short-cut is known.

Character of Froth. The nature of the froth made by the pneumatic method has the distinctive characteristic of being unstable or ephemeral, that is, it quickly dies when removed from the action of the injected air. The bubbles composing the froth, being generated under a hydraulic pressure varying from 15 to 40 inches, on rising above the water and to the froth-level, burst by reason of the lower surrounding atmospheric pressure. On bursting, they release the mineral attached to them, but this in turn is caught up by those bubbles immediately following behind. The instability or stability of the bubbles will depend, to some extent, upon the oil used and the nature of the gangue. Pine-oil makes a very brittle froth, which dies immediately on arriving at the surface. Creosote and light oil make a more elastic envelope, which at times will expand into bubbles 3 to 4 inches in diameter before bursting. The pine-oil bubbles will rarely be over ¼ or ½ inch diameter. Castor-oil, olive-oil, candle-makers' oil (oleic acid), palm-oil, sperm-oil, and other oils of a lubricating nature, have in general been replaced by oils more or less soluble or miscible in water—such as turpentine, pine-oil, and all the coal and wood-tar distillations. The very volatile oils, such as naphtha, gasoline, ether, alcohol, seem to serve very little purpose except as a means for making the pitchy ingredients of the tars more soluble or miscible.

A large, coarse, and elastic bubble seems necessary to the recovery of coarse-grained mineral, but for the very fine or colloidal mineral, a small and comparatively brittle bubble is necessary.

Power. The National Copper Co., using approximately 950 cubic feet of air at 4-lb. pressure, and treating 500 tons per day on 8 roughers and 2 cleaners, required 35 hp.; this equals 3.5 hp. per cell, or 12.53 tons per horse-power, or 1.25 kw.-hours per ton.

Another company using approximately 9600 cubic feet of air at 5-lb. pressure and treating 2400 tons per day on 48 roughers and 12 cleaners, requires 210 hp.; this

equals 3.5 hp. per cell, or 11.45 tons per horse-power, or 1.56 kw.-hours per ton.

The Inspiration experimental plant, using approximately 950 cu. ft. of air at 5-lb. pressure and treating 200 tons per day with 4 roughers and 1 half-size cleaner required 24 hp.; deducting 4 hp. for two 2-in. centrifugal pumps, this equals 20 hp., or 4 hp. per cell, or 10 tons per horse-power, or 1.79 kw.-hours per ton.

A maximum figure would be 2½ kw.-hours per ton of feed, using 5 to 5½-lb. air-pressure, generated by a Roots or Connersville positive blower.

Summarized, my estimate on a 2000-ton plant will stand approximately as follows, in cents per ton of feed:

Labor	1.25
Oil	2.50
Maintenance	0.50
Power	2.50
Total	6.75

On a plant of 250 tons the extra labor would bring it up to approximately 10c. per ton. Actual figures from a large plant of over 2000 tons gave 6.1c. per ton. The

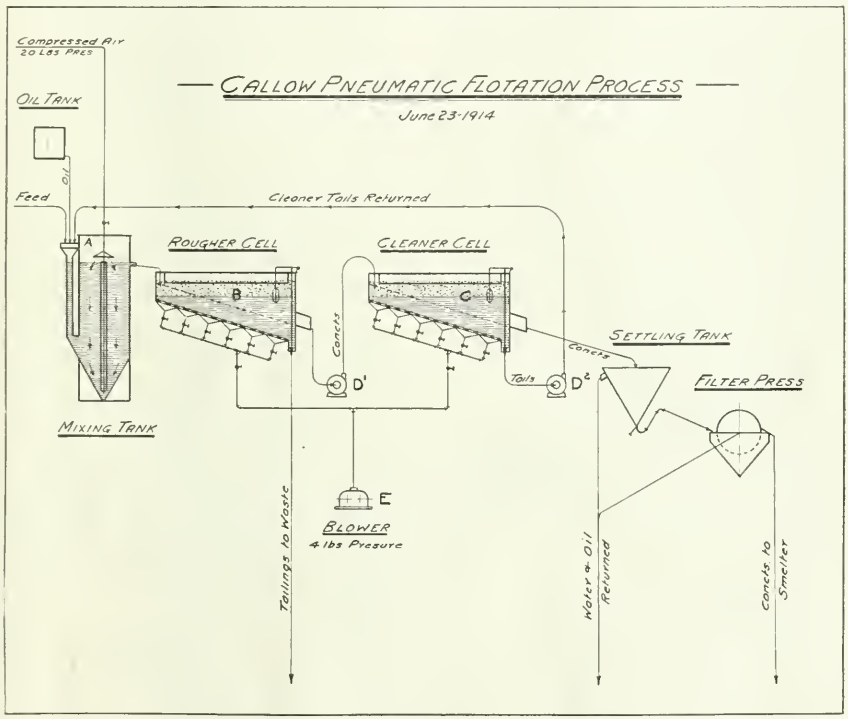

Fig. 5.

Cost. The oil-mixtures generally in use will cost from 1.25c. up to 3c. per lb. depending on the proportion of cresol and other high-priced oils used, but 1½c. per lb. will be a safe average on most ores. A consumption of 1 to 1½ lb. per ton or from 1.25c. to 4.5c. per ton of feed, say 2½c., would be a safe average. The labor, of course, will vary with the size of the plant. At one plant consisting of 60 cells, two men per shift operate the entire plant, equivalent to a cost of 1½c. per ton. One man per shift on a 250-ton plant will mean a cost of 5.4c. per ton in maintenance. Assuming a life of three months per blanket and 50 tons per cell and an allowance for repairs to blowers, motors, pumps, etc., we have ½c. per ton as a liberal estimate.

Power at 1c. per kw.-hour ($60 per hp.-year) and 2½ kw.-hours per ton equals 2.5c. per ton of feed.

flotation feed in this case represents 60% of the crude-ore tonnage or 3.5c. per ton of crude ore treated.

Theories. So far no satisfactory explanation of flotation phenomena has been advanced. At my instigation and under my direction, a large amount of research work has been done in an earnest endeavor to formulate some logical explanation, and perhaps to find some scientific way of conducting experiments in lieu of the empirical methods now in vogue. While this purpose has not yet been fully attained, the experiments have resulted in the formulation of a theory that appears to be well grounded and that may prove of value to others engaged in this branch of metallurgy.

Much work has been done at the Mellon Institute at Pittsburg under the direction of Raymond C. Bacon, and lately by James A. Block at the local station of the U. S.

Bureau of Mines. The results of some of this work are summarized in the following statements:

In considering the connection between flotation phenomena and the physical properties of the minerals concerned, there are two parallelisms to be noticed:

First: It has been noticed for some time that the minerals which floated were not easily wetted by water, while those which were easily wetted did not tend to come up with the froth. This is the basis of about the only theory that has been widely circulated up to this time. It is well stated by Hoover in his book, 'Concentrating Ores by Flotation,' the first authoritative publication on the subject.

Second: There is a parallelism between certain electro-static characteristics and the flotation properties of ores, as will be explained later.

In the theory first mentioned, it may be demonstrated by a consideration of surface tensions and contact angles that certain floatable minerals, such as galena, will float on the surface of still water, while gangue particles, on the other hand, possess a greater adhesive attraction for the water than the water's cohesive attraction for itself, and are therefore drawn through the surface film into the interior, where they sink because of their greater specific gravity. These properties of floatable minerals and gangues are increased by the presence of oil and acid. Oil sticks to galena with greater tenacity than it sticks to silica, and an oil surface is still less easily wetted than a galena surface. The acid in the water causes a still greater difference in the various surface tensions. This, it seems, is without question the explanation of such flotation as is obtained by the MacQuisten process, in which the ore particles are lifted to the surface and those remaining are removed by skimming the surface layer of the liquid.

As regards the second parallelism mentioned, it has been noticed that extremely small amounts of certain colloidal impurities, such as saponine or tannine, were detrimental to flotation, while others, such as Congo red and methyline blue, did not interfere, and were, if anything, beneficial. In classifying these, the injurious ones generally came under the head of what physical chemists call electro-negative colloids, while electro-positive colloids were not harmful. This classification is derived from the fact that suspended particles will generally migrate when placed in an electric field, and the classification comes naturally from the direction of their migration. This migration is called electro-phoresis, or electrical endosmose, and is the result of the fact that the liquid containing the particles forms contact-layers around them, similar to the surface-films formed when liquids come in contact with air. These contact-films almost invariably have a difference of potential between their inner and outer surfaces. The film of an air-water contact has, for instance, a difference of 0.055 volts[1], and other contact-films have similar charges. This causes the particles to act like charged solids, and to be attracted by electric charges of opposite sign.

[1]*Philosophical Magazine*, 1914, 27:297 and 28:367.

The charges on solids and non-miscible liquids can be conveniently studied on the stage of a microscope.

This work led naturally to the study of the charges exhibited by various ores and minerals, and in that work an interesting parallelism was observed; namely, that floatable minerals seemed to have positive charges and non-floatable gangues negative charges.[2] Some gangues were found with positive charges, but they were characteristically hard to handle, having a tendency to come up with the froth. These charges sometimes vary with the acidity or alkalinity of the liquid, and, this variation is not inconsistent with the effects of acidity or alkalinity on the flotation of ores.

It has been noticed that these electro-static properties depend on the condition of the surface of the particle and not upon the composition of the mass. For instance, lead oxide, which is ordinarily negative or neutral, when covered with a sulphide coating takes upon itself a positive charge.

Although these charges are small, recent work on the coagulation and deflocculation of slime, on the coagulation and dispersion of colloids, and along similar lines, show that these contact-film charges have an important bearing on the dispersion or coherence of particles suspended in liquid mediums. In fine suspensions and in colloidal solutions, these charges may often be neutralized by the introduction of oppositely-charged ions, and precipitation will generally take place whenever these charges fall below certain limits. Oppositely-charged contact-films have a general tendency to absorb each other, and to coalesce, while similarly-charged films, if their charges are great enough to overcome natural cohesiveness, do not seem to coalesce, but to repel each other, and if the weight of the particles is small enough in relation to their size and surface, permanent dispersion will take place, the particles distributing themselves through a liquid in much the same manner that a gas will fill a container.

In view of the above observations, it seems possible that flotation is due to differences in polarity in the charges on the various particles of ore, and on the bubbles. Since oil contact-films and air contact-films have both been proved to have negative charges, the positively-charged minerals might adhere to either. The bubble-mantles in a flotation machine are undoubtedly composed of oil, or of oil in emulsion, since pure water alone will not froth. The same forces, then, that cause oppositely-charged colloids to agglomerate and precipitate, cause the minerals to adhere to the oil-covered bubbles; and the same forces that keep the particles of an oil emulsion dispersed, keep the gangue-particles repelled from the bubbles.

Expressed briefly, the theory is as follows: That oil flotation is an electro-static process. It is a scientific fact that when a solid particle is suspended in water, the water will form around the particle a contact-film that generally possesses an electric charge, the amount and

[2]Kolloid Chemische Beihefte, 2:84; Zeit. für Physikalische Chemie, 89:91, 1914.

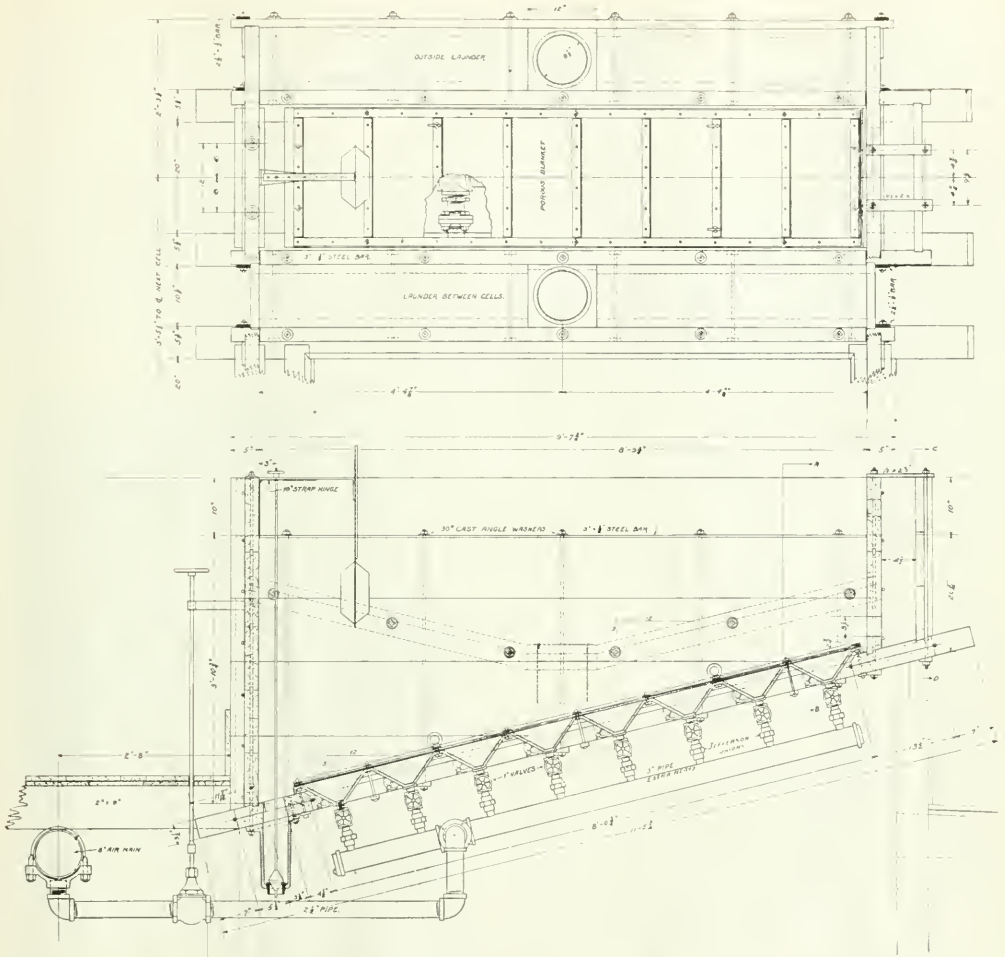

FIG. 6. PLAN AND SECTION OF THE CALLOW FLOTATION MACHINE.

polarity of which will depend upon the nature of the surface of the particle and the electrolyte in which it is suspended. The presence of these charges can be demonstrated by the fact that the particles possessing them will migrate when placed in an electric field. It has been demonstrated that floatable particles have charges of one polarity (positive), and that non-floatable particles have charges of the opposite polarity (negative), and that the froth is charged negatively and so attracts the positively-charged or floatable minerals, and repels the negatively-charged or non-floatable ones. It is this, it is believed, that causes the floatable minerals, such as galena or sphalerite, to adhere to the froth and rise, while the gangue-minerals, such as silica and limestone, remain in the liquid where they can be discharged as tailing.

A HUGE BLAST, breaking 75,000 tons of rock, was made at the H. Frazier limestone quarry, Fort Spring, West Virginia, in September. Fifteen holes were used, each 6 inches in diameter and all but two were 125 ft. deep; they were spaced about 15 ft. apart with a burden at the bottom of from 20 to 35 ft. In each hole was charged 400 to 500 lb. of 60% Du Pont gelatine on top of which was put 150 to 600 lb. of quarry-powder. On top of the charge was placed 20 to 30 ft. of clay stemming, while in ten of the holes the charge was separated near the centre by 10 to 25 ft. of clay. The charges were fired electrically by the superintendent F. R. Anderson. About half the stone was broken to one-man size and none was thrown over 100 yd. from the face. A total of 60,500 loose cubic yards or 75,000 tons was broken, an average of 5½ tons per pound of explosive.

Diamond-Drilling

By P. B. McDONALD

In much the same manner as the introduction of the machine-drill has benefited rock excavation by rendering it quicker and easier, the diamond-drill has expedited mining exploration. Diamond-drilling offers a convenient, speedy, even if only approximate, method of ascertaining the nature of a large extent or volume of rock. It is particularly helpful in obtaining prompt results at depths that sinking or tunneling would much delay, or in making a preliminary test over a wide area. Thus, during the Porcupine boom, the Dome Mines Syndicate wished to know at once whether its big hump of gold-bearing quartz possessed any continuity or was merely a surface blow-out. So, in addition to sinking three 50-ft. shafts and driving several hundred feet of drifts, it pointed some diamond-drill holes at an angle into the surrounding swamp to intercept the supposed orebody in depth. Had the cores obtained been barren of gold, it would have been a severe check to the exploration, but as the borings tended to confirm the evidence gained in sinking and driving, the promoters were prompted to go ahead with the elaborate developments of a mine and mill.

To a considerable extent diamond-drilling is useful in conjunction with sinking and driving. Thus an exploratory shaft may be deepened, and in its bottom several horizontal holes pointed off at various angles around a circle, to intersect possible orebodies. Or in a long drift underground, the old custom of exploratory cross-cuts may be supplanted by horizontal diamond-drill holes on both sides at intervals of, say, 100 ft. for the tapping of parallel orebodies or veins either in the foot-wall or hanging wall. These bores serve the exploratory purpose nearly as well as cross-cuts, and cost perhaps a half or a third as much per foot.

In the Lake Superior region, both in the Copper Country and on the Iron Ranges, diamond-drill exploration has been particularly developed. The utility of the diamond-drilling is suggested at once by the geological structure of the two districts. In the Copper Country the Keweenaw series, which contains the copper-bearing beds, is composed of a multitudinous succession of igneous flows intercalated between conglomerates, marking periods when the sea encroached on the land. These igneous and sedimentary beds are parallel to each other, and dip at from 30 to 70 degrees northwest, eventually flattening out under Lake Superior. The copper lodes, consisting of such occasional amygdaloids or conglomerates as have been mineralized, form only a small and irregular proportion of the whole. Thus, extensive diamond-drilling at approximately right angles to the dip of the formation, so as to cut the maximum number of beds, has become popular for preliminary exploration in depth, especially since the obviously rich lodes have been exploited. Operators in that region remember the interest taken in diamond-drill exploration several years ago when Lake, Indiana, Old Colony, Mayflower, etc., were being boomed on reports of diamond-drill cores. Thomas F. Cole has been employing the diamond-drill freely in the explorations of the Keweenaw Copper Co. where a large area of land was to be tested; and the Naumkeag Copper Co. and White Pine Extension did more or less drilling in their ventures farther south.

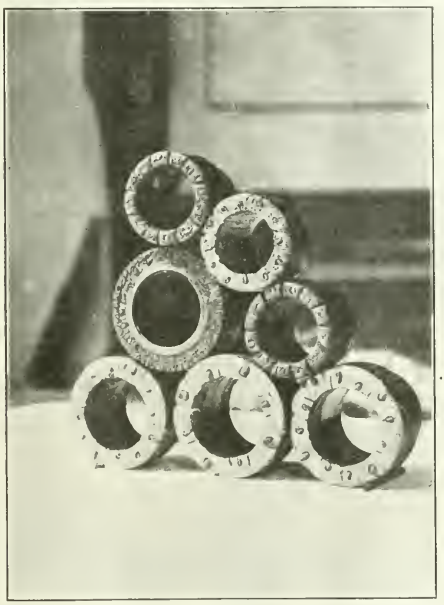
There has been even more diamond-drilling on the Iron Ranges than in the Copper Country. As soon as the ore deposits having outcrops were located, diamond-drills and churn-drills were employed in hunting for orebodies at depth. A great number of the iron-ore deposits occur as concentrations deep down in folds of the underlying slate, or caught on more or less impervious dikes, where the leaching of water during geological ages has stored up irregular masses of ore in all sorts of shapes and positions. Drilling campaigns of considerable expense have been undertaken by sinking holes to two or three thousand feet through slate or jasper in the hope of hitting an iron concentration in a deep fold at the bottom of the formation. Angle-holes of every variety have been pointed in and around the complicated structural features of the Iron Ranges, in search of the extremely various orebodies. When a drill-hole has once cut an appreciable thickness of iron ore, say a hundred or two hundred feet, it is usually attempted to determine the shape and size of the mass by more holes. In many cases the tonnage of ore is thus estimated correctly to the nearest million tons before a shaft is sunk or any plant erected. Some companies, however, after having drilled enough holes to indicate a reasonably large orebody, do not try to delineate its entirety, but put down one or two more holes to find a portion of the surface not underlain by ore to serve for the mine-buildings, and leave the ultimate extent of the deposit to be determined later by driving and sinking.

The immediate results of diamond-drilling are core and sludge. From drilling a 1000-ft. hole in rock each five feet of drilling may give an average of one foot of core, making 200 ft. of core obtained to judge the formations that have been penetrated. The other four feet of core becomes pulverized and washes up the hole as sludge, to be caught and dried in a special settling-box. It is fortunate when a full five feet of core is obtained for each five feet of drilling, as may be done in hard and homogeneous rock. An inspection and assay of such a complete core is wholly satisfactory and descriptive of the formations traversed. Where only a fractional part of the core is obtained, it is necessary to consider the

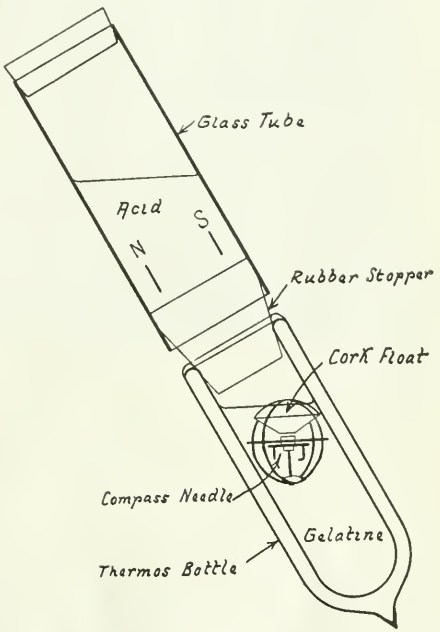
sludge carefully, as the core itself naturally represents the harder portion, which is likely to be lean and poor. In drilling through a hundred feet of an oxidized ore like hematite, if only one-fifth of the core be obtained in the core-barrel, the assays of the sludge should be given much more weight than those from the core; because, as can be computed by knowing the size of the drill and core, the core obtained represents only an insignificant part of the boring returns. The exact ratio for averaging core and sludge assays for each five-foot section of drilling can be figured exactly by measuring the bit, computing the relative volumes of core and sludges that should be recovered, and making out a convenient reference-table good for all lengths of core obtained. Special care should be taken when drilling to catch all the sludge.

The cost of diamond-drilling varies widely. It is generally more than $1 per foot (which might be the cost in a homogeneous soft shale or schist) and is usually less than $5 per foot (which figure is not unusual for broken hard jasper.) On one job of several thousand feet of drilling near Negaunee, Michigan, where working conditions were fair, four contractors bid $4 per foot, $3.25, $3, and $2.50. In this instance the work was in a swamp where water was convenient, but roads had to be improvised for short distances; the rock was silicious slate and hematite. The cost of the diamonds in the bits may represent from 10% of the total cost of drilling to 50%; black diamonds are worth nearly $100 per carat, and wear constantly in the drilling. The other items of cost are labor and fuel. A company on the Iron Ranges may spend $25,000 to $50,000 on diamond-drilling an orebody before sinking a shaft. It is in such large-scale operations that the diamond-drill is most advantageous. For shallow and small high-grade orebodies, the operator is likely to get more knowledge and satisfaction from sinking, driving, or cross-cutting, by which he can inspect results underground in place.

Strange occurrences sometimes complicate diamond-drill operations. Drilling into hard strata at an angle may bend the rods enough to turn the line of the hole into a big curve and cases have been reported of the bit even emerging to surface again, perhaps several hundred feet away. Test-bottles of dilute hydrofluoric acid are used to determine the dip of the hole at any desired point. I remember how one young engineer lowered a bottle of full-strength acid, only to pull up and find that the bottle had been eaten away by the acid, leaving only the neck. In careful or deep drilling where accuracy is important, surveying of the holes is worth many times its cost. This can be accomplished by a drill-hole compass, of which George Maas, of Negaunee, Michigan, holds the patents and which has been perfected by E. E. White of Ishpeming. The compass floats in liquid gelatine, which solidifies in the containing thermos-bottle or glass tube. The Cleveland-Cliffs Iron Co. has made over a thousand such tests in the last five years. Vugs or caves, sometimes of surprising size, exist in certain rocks and districts, requiring cementing or plugging in one way or another, before it is possible to proceed and properly recover the sludge-water. One drill-crew dumped several tons of oats, manure, cement, etc., into a



DIAMOND-DRILL BITS SHOWING DIAMONDS SET FOR BORING.



FLOATING COMPASS FOR SURVEYING DIAMOND-DRILL HOLES.

drill-hole before effecting a stoppage. Reaming of holes and lining with pipe is necessary in broken formations to effect a return of the water. Losses of the bit in the hole are not uncommon, necessitating tedious 'fishing' with the long line of rods to recover it. Separate diamonds may fall out, or a careless dropping of the rods may shatter the half-dozen diamonds in the bit, worth probably several thousand dollars. A drill-runner who drops the rods usually clears out for a new district without hesitation.

On the Iron Ranges a great deal of attention is devoted to the proper interpretation of diamond-drilling results. Special care is taken in recovering all the sludge in a large wooden settling-box; sludge and core assays are made for each five feet of ore-formation cut, and then carefully averaged in proportion to the amount of core recovered. Maps showing the holes are kept up to date, as well as such information on neighboring holes by other operators as can be obtained, and sections of drill-holes and their results are conveniently tabulated on tracing-cloth for making blue-prints.

The Study of Mining Geology

In a lecture to the students of mining at the University of California, John A. Burgess had, in part, the following to say concerning the 'Study of Mining Geology':

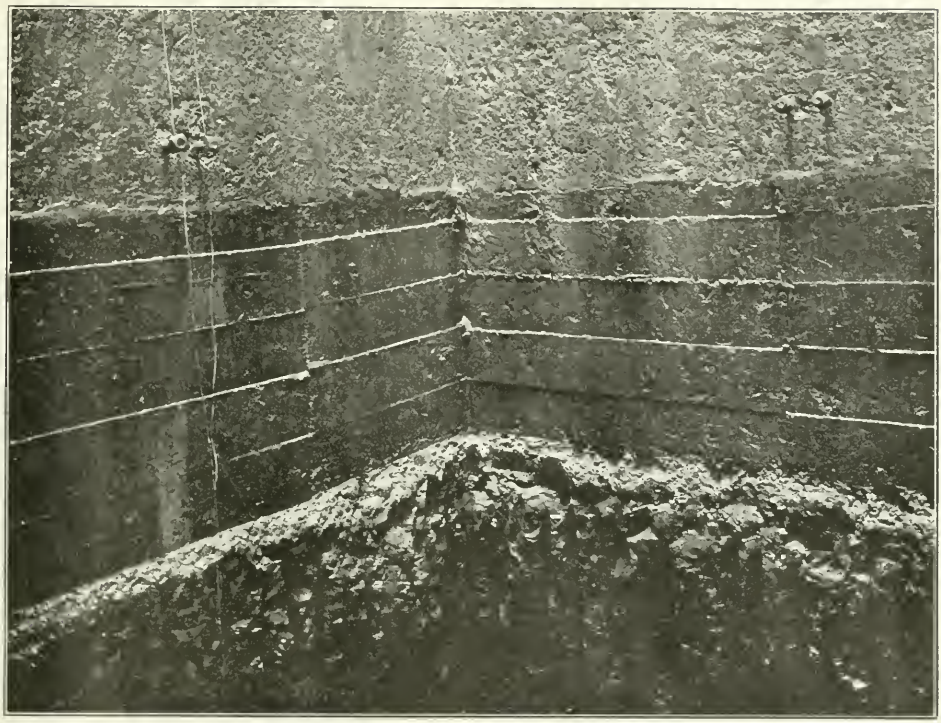
A man who has an absorbing interest in some particular line of work, who bends every effort to learn all there is to be known about it and to make himself proficient, will seldom fail to find an opportunity to exercise his knowledge; his pecuniary reward and the extent to which he becomes known in his profession will depend largely upon his business ability and his personality. If you are determined to be a first-class mining geologist no one can keep you from it. Your interest in the subject, your determination to pay the price in study, application, and perseverance, and your willingness to be known as a sort of a crank on geology are what will tell the tale; and when you do become proficient you will show poor business ability if you do not find employment in your chosen work. If the picture I have drawn seems a dark one, remember that I am making it so to give encouragement to the one who may have to travel such a difficult path. Usually the way is much more direct.

The new graduate in his first position is an apprentice. He should endeavor to arrange to serve his apprenticeship where it will have the greatest bearing on his chosen work; but there is no work, which, if it is done well and with interest, will not be of benefit in the way of experience. You will be surprised to see how things you have learned to do, apparently having no connection with your present work, come into play at unexpected times. My work as a boy, spraying trees in an orchard made me familiar with the Vermorel spray-nozzle, which is now used in connection with continuous filters, and through my knowledge of it I believe it was first applied to this class of machinery in our mill at Wonder, Nevada. Farm work, carpenter work, mechanical work, bookkeeping, anything whatever that you have learned to do well, is apt to be of service in your work as a mining engineer. The more experience you have had outside of strictly mining lines, the better engineer you will be. Concentration of effort on your specialty is, of course, essential; but, especially in one's younger days, it is not always possible to secure just the kind of employment one would choose. Valuable experience may be had, however, at any kind of work, and it would be a waste of experience, the worst kind of a waste, to feel contempt for any class of labor and fail to get what benefit may be secured from it. Make your breadth of experience, where it is forced on you, compensate for the temporary failure to acquire the special experience for which you are seeking.

In studying ore-formations, note dips and strikes of all faults and strata; take specimens of all rocks and map the veins with particular care. You can only map what you see, but be sure that you see all there is to see. Make all notes so clear that they can be understood readily by another geologist; unless you adopt this practice you will find yourself puzzling over your own notes in later years.

Ore often lies in shoots that have an unpleasant habit of coming to an end unexpectedly, either laterally or in depth, while on the other hand many an apparently worked-out mine has been re-opened with profit. In many veins the ore shows a preference for the hanging wall, the foot-wall being practically barren; this is sometimes caused by the vein being a compound one, having been deposited at two distinct periods; in this connection detailed study of drifts and old stopes may give evidence. Features to be noted are the degree of oxidation, whether the minerals are primary or secondary, their relation to the water-level and to the country-rock.

Mountains are classified by James Park in his 'Text-Book of Geology' as (1) Folded mountains, including all the great mountain chains of the globe that are known to consist of uplifted crustal folds; these are sometimes known as Alpine. The Sierras are of this type. (2) Volcanic mountains, hills, or ridges piled up by the accumulation of lavas and other material ejected from a volcanic vent or fissure, such as Mt. Shasta. (3) Plateau-mountains, are due to lesser folding than (1) and are subdivided into (*a*) Uinta structure, as in the Uinta mountains of Utah, which consists of two monoclinal flexures bending in opposite directions with a broad plateau between them. (*b*) Park Plateau structure, found in the Yellowstone Park, where Mesozoic rocks have been bent over a plateau-like complex of granites and gneisses and then denuded so that their truncated ends stand up at high angles against the central mass. (*c*) The Kaibab structure is a modification of (*a*). (4) Block-mountains have been formed by the displacement of large blocks as in Colorado. 'Horsts' are blocks that have remained elevated while the surrounding area has sunk. Residual mountains are left when the surrounding country has been eroded.



A TYPICAL CONCRETE SAND-SHAFT SEALED TO BEDROCK.

Grouting in a Shaft

By J. R. REIGART

*The Francis shaft of the Cleveland-Cliffs Iron Co. was sunk through quicksand to bedrock, a distance of 102 ft., by the Foundation Company of New York, which completed the work in June 1910. A concrete seal was put in the bottom and the shaft turned over to the mining company.

The shaft through the sand is circular, 17 ft. diam. inside, constructed so that it might be continued at standard size, 10 ft. 10 in. by 14 ft. 10 in. inside measurements, rectangular, with two skip-compartments, a cage-compartment, and a ladder and pipe-way. Work was resumed in the spring of 1911, but continued only long enough to put in the steel dividings, and to drill a number of holes through the seal to ascertain the flow of water to be handled. The holes all struck water in two or three feet, at a pressure of 40 lb., so that any two holes gave a No. 9 Cameron pump all it could handle. As fast as the holes were drilled, wooden plugs were driven into them. At first any handy pieces of wood were used as plugs, but these did not stop the water. Accordingly regular soft-pine plugs, from 3 to 3½ ft. long and tapering from 4 to 6 in. were made in the shops. With these the holes could be made water-tight.

These holes demonstrated the fact that a large flow of water would be encountered as soon as the seal was broken, and also that the slate probably was broken to a considerable degree. It was readily seen that the water would have to be stopped before continuing, or the shaft could be sunk only with the greatest difficulty and expense, if at all. The Foundation Company might have continued the shaft by its caisson process except for the fact that at the time bedrock was struck the men were working under 47-lb. air-pressure on 15-minute shifts. This was not only exceedingly expensive, but hazardous.

The rock at the bottom of the shaft being irregular, the thickness of the seal varied, but it was supposed to average 24 inches. The finding of water so quickly

*Abstract of paper presented at the Lake Superior Mining Institute in 1915.

seemed to indicate that the seal inserted by the Foundation Company had not formed a good contact with the rock. At this point work was discontinued and was not resumed until February 1, 1915.

When work was begun various means were discussed for permanently stopping the water, and it was decided to drill inclined holes around the inside of the shaft, at such an angle that they would reach beyond the outside circumference of the wall of the shaft; neat cement would be forced into these holes under air-pressure until all the water-bearing cracks and crevices were filled, making water-tight ground through which the shaft could be sunk with safety. It was feared that there was an open space between the seal and the rock covering a portion of the area of the shaft. If this were the case, the pressure exerted on the cement to force it into the holes would be transmitted against the bottom of the concrete seal and develop an enormous pressure. Thus there would be danger of breaking through it, which would be a serious matter. As a precaution 3-in. planks were set on edge 8 in. apart, like joists in a floor; on top of these and at right angles to them 12-in. square timbers were put across the shaft 4 ft. apart and spragged with stulls to the steel sets above. Wherever there was any space between the joints and the seal, wedges were driven so that, should there be tendency for the concrete to yield, the pressure would be instantly transmitted to the bracing. This covered the bottom of the shaft but left space for drilling holes until the space below the seal had been filled and the reinforcing could be removed with safety.

A platform was built 6 ft. above the bottom of the shaft; on this were placed the air-pressure grout-machine, the valves for operating the low and high-pressure air-line, and a No. 9 Cameron pump. On the set above, two other pumps were installed, a No. 8 Cameron and an Alberger electric pump. This gave a pumping capacity of from 1400 to 1600 gal. per minute. A 3-in. pipe-line for conveying the grout, which was to be mixed on surface, was hung so that it emptied directly into the grout-pan. The tank used was the Caniff machine. It consists essentially of an iron tank 24 by 48 in. with connections for admitting air at both the top and bottom. When the tank has been charged, air is blown in at the bottom to agitate, thus insuring a thorough mixture and preventing the grout from setting. This air is then shut off and air admitted at the top to eject the grout. The hose between the tank and the grout-pipe was 2 in. in diameter, and of extra quality rubber warranted to stand a pressure of 300 pounds.

The grout pipes were made from 1½-in. standard pipe 3 to 4 ft. long. To the end to be driven into the hole, a bell made from a piece of 2-in. pipe 8 ft. long was welded. The 1½-in. pipe is pushed into the large end of the bell until its end is even with the unexpanded end of the bell, the pipe being welded at this point. A unit of operations was the drilling and grouting of 6 holes spaced at equal intervals around the circumference of the shaft, numbered in the order drilled. To drill these 6 holes and put in the grout-pipes was a day's work for a crew of two men and a foreman. On the following day these holes were grouted, and for the next two, work was suspended to give the grout time to set and harden. At first only one day was allowed for this, but it proved insufficient where a large amount had been put into one hole. A total of 41 holes was drilled and 27 were grouted. As the work progressed the holes were drilled deeper, until 14-ft. holes at an angle of 45° encountered no water. Finally a few holes, No. 38, 39, 40, and 41, were drilled in the interior of the shaft to reach any seam that might run parallel with the inclined holes, and which these holes might have missed. As no water was encountered, all was now ready for sinking.

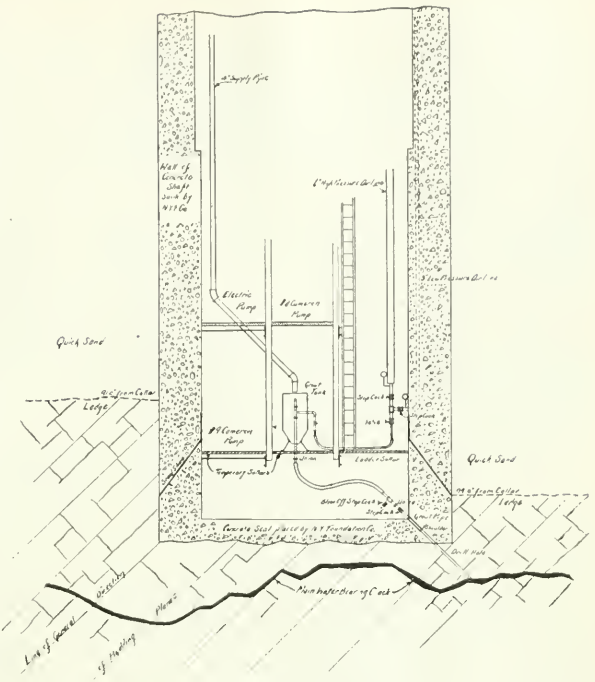
Grouting was started on the morning of March 26. A gauge attached to one of the grout-pipes showed a pressure of 43 lb. It was surmised that there were large areas to be filled, so that the only pressure to be overcome would be the hydrostatic head. Therefore 60 lb. was used in the first operations. The mixture was thin, being composed of two 12-quart pails of cement and four 12-quart pails of water. Consequently the grouting went so slowly that the mixture was changed to one bag of cement and three 12-quart pails of water to a batch. It is important that the mixture be thin enough so that it is perfectly fluid. No sand was used in these mixtures, but it may be, if desired. The cement was screened over a heavy wire screen running 4 meshes per inch, to take out lumps. The first hole grouted was one drilled in the operations of 1911. Some of the plugs put in at that time were not tight enough to keep the thin mixture of grout from being forced back into the shaft. Wherever possible, these old plugs were replaced by regular plugs, but there were some that could not be removed and that could not be made tight enough to withstand the grout. Accordingly bran was forced into the hole, and then a richer mixture made with one bag of cement per batch. The hole soon filled and there was no more trouble from this source.

From the first holes, in particular, the water brought up fine sand and small pieces of broken rock. With the first of these, the water was stopped as soon as the grout-pipe had been made tight, but later the stopcock was left open and the water allowed to flow for a period of 10 minutes until the water became clean and free of sand. The effect of this was seen later when the bottom of the shaft was removed; in holes that had not been allowed to clear themselves the grout was mixed with the sand in the seams and could be readily taken from the cracks with a pick, but wherever the holes had been allowed to clear themselves the cracks were filled with hard clean cement. Hole No. 113 required 332 bags of cement. After two days' work with 60 lb. of air, it was decided that the seal and bracing were strong enough to stand a pressure of 80 lb., and this pressure was used thereafter. Some holes that would not take grout at 80 lb. were given a pressure of 150 lb. This pressure was used also toward the completion of the holes when they began to take grout slowly at 80 lb. When the holes were taking grout freely we operated at the rate of a batch of grout every 50 seconds, which was as fast as the cement could be screened, mixed and sent

from surface. The crew on surface consisted of five men, one man bringing the cement from the store-house, one man screening, one measuring the charges, and two mixing and stirring with paddles to insure a thorough mixture. In the shaft the foreman operated the grout-machine, one man the blow-off valve near the grout-pipe, and one the stopcock on the grout-pipe.

Where the openings to be filled are as large as they were in this case, an 80-lb. pressure will suffice, but where the seams are smaller, higher pressure is not only desirable but necessary to overcome, in addition to the hydrostatic head, the friction in the seams. The farther the grout can be forced, the more effectively will the water be stopped. If high pressure could have been used from the beginning, this particular job could have been finished with fewer holes. The grouting was completed on April 26, a month after starting.

When it had been demonstrated that the water had been stopped, the rectangular shaft was started. Holes 8 ft. deep were drilled around the perimeter of the rectangle 2 ft. back from the line of the shaft and as close together as possible. The first 4 ft. was then broken by mailing and with wedges and feathers. The concrete seal was the hardest part of this work as the rock broke easily along the slips and joints. For the next cut the holes were drilled on the outside of the shaft as before and the ground broken by drilling and blasting with light charges of powder, not over a half-stick per hole, and never over two or three holes at a time. This was repeated until the shaft was 18 ft. below the shoe of the concrete sunk by the Foundation Company.



CROSS-SECTION OF SHAFT SHOWING CRACKS IN THE ROCK FILLED BY GROUTING.

SCALE 1:2'

● Hole showing water and grouted
○ Hole showing water but not grouted
⊖ Hole showing no water but grouted
○ Hole showing no water and not grouted

To secure further the portion of the shaft that had been grouted, the sides of the shaft traversed by the filled seams were lined with a reinforced-concrete wall averaging two feet thick. Hitches were cut 12 ft. below the shoe and 9-in. I-beams put in for bearers along the small dimension of the shaft. To these bearers, hanging-bolts were attached. Forms were then constructed along the line of the shaft from the top of the concrete seal to 2 ft. below the bearers. First, however, $1\frac{3}{4}$-in. cramp-rods, spaced 2 ft. apart, were put in the walls of the shaft. Wire rope, pieces of expanded metal, iron bars, pieces of old angle-iron and channels were fixed for reinforcing. The space was then filled with concrete having a composition of one part of cement, one part of sand and gravel, and two parts of broken rock. This was given two days in which to set and then work was resumed.

When the bottom of the shaft was removed, the

conditions were not as had been anticipated, as the seal had a good contact with the rock over the entire area of the bottom of the shaft. What we did find was a large seam varying from 2 to 6 inches wide cutting across the entire shaft within a few inches of the bottom of the seal.

The cost of the work up to August, when two shifts could be employed and sinking proceed in the usual way, was as follows:

Grouting	$1,431.74
Sinking	1,882.45
Timbering	885.15
Concreting	407.42
Total	$4,606.76

When the advantages gained are taken into consideration, the method seems inexpensive. To pump the flow of water, if it had not been stopped, is problematical, but 4000 to 5000 gal. per min. is probably a low estimate. If the shaft could have been sunk to the present depth by ordinary methods, and the water could have been caught and pumped, the expense of installing the necessary equipment and of pumping such an amount of water over the period of years comprising the life of the mine would be enormous. It is obvious that a company could afford, if necessary, to spend several times the above amount to get the result obtained. The method of grouting water-bearing seams can be used at any depth provided sufficient air-pressure is available. For effective results, the air-pressure should be from 100 to 200 lb. over the hydrostatic head. No further trouble from water is anticipated in the sinking of the Francis shaft, as a diamond-drill hole was found at a depth of 865 ft. in the bottom of the shaft and no water was coming from it.

Arizona and Modern Mining

By L. D. RICKETTS

*Most of you know my State—its glorious hills and deserts in the south, its forests and soul-inspiring canyons and summits in the north. One is impressed by its bigness and intensity and grandeur; but one must be impressed also with its vast actual and potential resources as a copper producing state.

Some years ago a wave of agitation swept the country over the conservation of our natural resources. The subject was not properly understood and there was much apprehension. Many advocated self-denial of the present generation in behalf of succeeding generations. Assertions were made that our mineral resources had but a short road to exhaustion and were being used up with reckless waste to the danger of civilization. Like all awakenings, the situation did good, but the chaff had to be winnowed out of the wheat, and of chaff there was a great abundance. The first fact that developed was the broad one that future generations would have the advantage of accumulated knowledge and would be in a better position to care for themselves, and that the present generation is, therefore, entitled to take from the earth that which it needs, provided always that such action is accompanied with a minimum waste and destruction. The second fact that developed was that while the richest deposits of our mineral wealth were being exhausted, the arts of mining and metallurgy were so rapidly advancing that leaner and hitherto unprofitable ore deposits were being brought to the point of profitable exploitation and by this means the actual quantity of the metals available in profitable ores instead of decreasing was increasing manifold.

This has been the work of the engineer aided by capital. But to accomplish his result the engineer has had to supplement individual effort with organization and committee work and to recognize that the field has become too large for any one man.

The great requisite was the power to recognize latent possibilities; the recognition of the importance of vast tonnages of mineralized rock, even if the metal-content be very low, together with the courage and earnestness to recommend the vast expenditures that modern mining and metallurgical problems now require, with a full sense of responsibility and to patiently wait all commercial results from the investment.

The second requisite was to recognize the limitation of the individual and the necessity of the association of a great variety of talent exercised by a large number of men into a working organization of ability, courage, and spirit. The whole question of the economical generation and application of power to mining and metallurgy had to be studied, mining methods had to be revolutionized in order that the efficiency of labor might be greatly increased and metallurgical methods had to be enlarged and vastly improved, in order that the ultimate percentage of recovery of the metal might be greatly increased and the unit costs of reduction tremendously decreased. And we have also had to study new processes and the means of utilizing by-products that have heretofore gone to waste.

The work in Arizona has been the result of the single efforts of no individual. Several splendid organizations have worked in parallel in the State, each guided wisely and ably by a united staff. And it is through this that my State has become the greatest copper-producing district in the world. It is through the united efforts and association of engineers, of capital, and of labor that Arizona copper mines and reduction works have sprung from that which a few years ago were but great masses of uncommercial copper-bearing rock, and some millions of tons of copper have been made available to the arts.

*Abstract of address at the Panama-Pacific Exposition, November 18, by "the Most Distinguished citizen of Arizona."

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WALLACE, IDAHO

MEETING OF THE A. I. M. E. IN THE COEUR D'ALENE.

The fifth annual meeting of the Columbia section (formerly the Spokane section) of the American Institute of Mining Engineers was held at Wallace, on November 19 and 20. A party of about 30 members and visitors went from Spokane on the first day, and these were met at Wallace by others from various parts of Idaho; the total attendance at the meetings, including local members and others connected with mining, was about 100 persons.

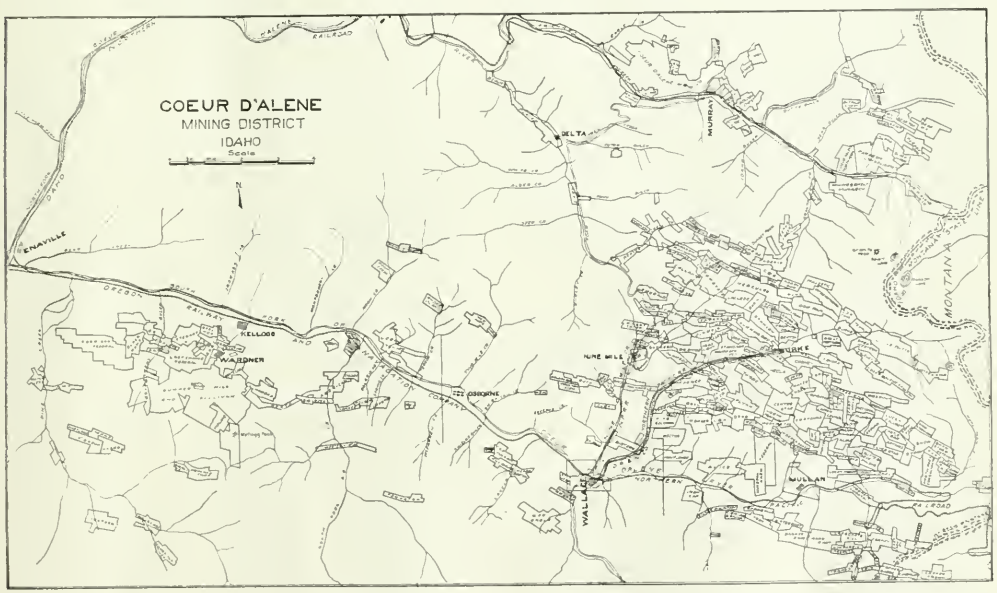
As a suit involving the question of extra-lateral rights was being heard in the local Court, the proposed afternoon session of the Institute was not held, most of the members attending the Court session instead to hear the expert evidence given. In the evening the meeting was presided over by Stanly A. Easton, of Kellogg, general manager of the Bunker Hill & Sullivan company, who on behalf of the Shoshone county members extended a hearty welcome to the visitors. The secretary, L. K. Armstrong, of Spokane, read a lengthy communication from the chairman of the section, Frank A. Ross, of Spokane, who had been prevented by illness from attending the meeting. Four papers were presented as follows:

(1) 'Progress in Ore-Dressing,' by D. Wilson Buckby, mill superintendent for the Stewart Mining Co., who dealt with recent developments in mill practice in the Coeur d'Alene district, the paper being an excellent presentation of a subject of general interest. In the course of the discussion that followed, flotation oils had attention, and in this connection M. G. Donk, of the Bureau of Chemistry, Washington, D. C., who is engaged in investigating the subject, asked for the co-operation of local mill-men in obtaining information relative to the possible production of pine oil from western woods, and data concerning the consumption of flotation oils in the district.

(2) 'Mine Accounting for Small Mines,' by J. E. Chapman, of the Federal Mining & Smelting Company.

(3) 'Zinc Smelting and Smelter Rates,' by W. E. Henry, of Spokane, district representative of the Empire Zinc Company.

(4) 'Leaching Zinc Ores,' by D. C. Livingston and W. M. Ellis, this being notes, illustrated by diagrams, on leaching tests made by students at the University of Idaho, Moscow.



The second day was occupied in visiting mines and concentrating-mills in the neighborhood of Wallace, including the zinc mine and mill of the Consolidated Interstate-Callahan Mining Co., the mills of the Success and Marsh companies, and a trip underground at the Bunker Hill & Sullivan Co.'s mine at Kellogg.

In the evening a business session was held, at which the result of the ballot for officers for the ensuing year was announced, as follows: chairman of the section, Stanly A. Easton; vice-chairman, Frederic Keffer, Spokane, Washington; secretary-treasurer, L. K. Armstrong, Spokane (re-elected). A banquet, provided by the local members, followed, and at this the vice-chairman, Rush J. White, gave place to Mr. Easton as chairman for the evening. Those who accepted the chairman's invitation to speak after the banquet were E. Jacobs, of Victoria, B. C., secretary of the Western Branch of the Canadian Mining Institute; Glenville A. Collins, chairman of the Puget Sound (Washington) section of the A. I. M. E.;

R. N. Bell, inspector of mines for Idaho; and J. M. Porter, one of the pioneer mining engineers of the Coeur d'Alene district.

After Mr. Armstrong had made announcements of particular interest to members, this most successful meeting of the Columbia section was closed, with thanks to local members and others for their hospitality and kindness.

TORONTO, ONTARIO

Cobalt, Porcupine, and Kirkland Lake Developments.—Consolidated Mining & Smelting Co. of Canada.

There is increased activity at Cobalt owing to the advance in the price of silver, and several companies which had curtailed operations are increasing their forces. Shipments of bullion are light, and there has been a disposition to limit the output sufficient to cover working expenses; but most of the companies are putting a good deal of energy into development work and the improvement of underground conditions.

Some important new discoveries are announced: The Kerr Lake company in trenching at the old Drummond mine has discovered a niccolite and smaltite vein 8 in. wide, assaying about 400 oz. silver per ton, and overlaid in places with shoots of plate-silver.——At the Mercer, formerly the Gould, operated under lease from the Peterson Lake company, a 2-in vein of high-grade ore has been cut in a raise from the 200-ft. level. ——The Chambers-Ferland is extracting rich ore from a vein found in a winze at the 400-ft. level, and is exploring territory adjoining the Nipissing vein systems.——The president of the Nipissing, E. P. Earle, states that the vein recently discovered in the Cobalt Lake fault is the most important development made by the company in the past two years. It is apparently 8 to 10 in. wide, and is worth from 1800 to 2000 oz. per ton.———At the Adanac a winze is being sunk from the 200-ft. level on a vein which is widening at depth, and shows niccolite, cobalt, and native silver.——A vein has been cut on the Shamrock, adjoining the Beaver, reported to assay 1500 oz. per ton.——The Temiskaming, which will shortly increase its mill capacity by 30 stamps, has declared a 3% interim dividend.——The English head office of the Mining Corporation of Canada has ordered the discharge of all alien enemies employed at the Cobalt Lake, Cobalt Townsite, and City of Cobalt mines. About 50 men, nearly all Austrians, have accordingly been dismissed.

At Porcupine, the Hollinger is opening the area to be served by the new central shaft under Hollinger hill. Three separate orebodies have been found in a cross-cut at the 425-ft. level. These are respectively 10, 6, and 4 ft. wide, and will assay $10 per ton. The shoot near the Millerton is improving in grade at depth. A contract for the head-frame over the central shaft has been let. The hoist to be installed here is of 5000-ton capacity, raising 5-ton skips.——At the Dome, the new five-compartment shaft is down over 50 ft. Good progress is being made in opening the seventh level, where there is now a considerable quantity of ore available.——The Schumacher, which is now producing regularly, has cut a station at the 600-ft. level, and will open this and the 500-ft. levels simultaneously.——In drilling from No. 4 level at No. 5 shaft, at the McIntyre, a mineralized belt about 15 ft. wide has been cut on the 600-ft. level, with an enrichment in the centre about 3½ ft. wide, which gives high assays. The main shaft on the McIntyre Extension is down 850 ft. A good orebody has been opened on the 300 and 400-ft. levels. The milling capacity of the McIntyre will be increased by 50% in January, and the plant will then be in position to treat ore from the McIntyre Extension and the Jupiter.

The Tough-Oakes at Kirkland Lake, is now operating both mine and mill with electric power. Underground development has lately been attended with highly encouraging results, some rich ore being extracted from both vein systems.——The Montana & Hecla Mining Co. has purchased the McGuire claims in the Goodfish Lake part of the Kirkland Lake district, and will sample them by diamond drilling——The Dominion Reduction Co. has dropped its options on claims held at Goodfish.

The Consolidated Mining & Smelting Co. of Canada, has sent out a circular to its shareholders in connection with the issue of new shares giving a statement of the affairs of the company. There has been a considerable expansion of its productive capacity. The zinc output for 1916 has been contracted for by the Canadian Shell Committee, at the request of which the company has undertaken the refining of copper. This will be carried on to a limited extent for a while, but it is expected to develop and involve the treatment of much of the matte and blister copper produced in British Columbia. The output of refined copper during 1916 will be taken by the Committee at a fair price. When plans now being carried out are completed, the lead-producing capacity of the plant will be increased 60%, and put on a more economical basis. The demand for lead during the past year has taxed the capacity of the furnace to the utmost, and the output has been sold for six months ahead.

LONDON

Munitions and Labor.—Dredging in Russia and Colombia.—Mining in Russia.—Burma Corporation Prospects.

Manufacture of munitions is now going forward at a comfortable rate, and we have time to think a bit of other things. Really surprising work is being done by the munition plants, and when the whole story comes to be told, there will be much more to be said for what was accomplished than of the 'muddling' of which for the last few weeks we have heard so much. Women have taken the place of the men with remarkable results, though *Punch* does represent a mistress as warning a maid who gives notice preparatory to taking a job in a munition plant, by saying: " You know, Mary, that if you go around there dropping shells as you have been dropping plates, you won't stay in the situation long." That is a libel. While so many maids have gone that there is even danger of the "knocker on the big front door" going unpolished some morning, the effect in the factories has been excellent. It is the universal report of the manufacturers that the output per operator has increased enormously, and that it has proved possible to put women not only on the unskilled but much of the skilled work, therefore releasing men to go to the front. I even heard last night of a salesman for an electric-goods house who proposed to enlist and let his wife handle his trade while he was gone. All this is not only helpful now, but extremely suggestive as to that dark future after the War, of which there are so many forebodings. It is already recognized that when the men come back, many of them will not stay here, but will go to the colonies. If it prove possible so to re-organize industry as to use better those who do remain, and to use the surplus of woman's labor that always exists here, the country will be industrially stronger even if 'the master's boots' are not always well polished. However that is a problem for the future. It suffices now to note that we are forwarding plenty of munitions, and still able to take contracts for mining machinery, even if we cannot for the present compete as fiercely for business as before. I note that the chairman of Fraser & Chalmers, Ltd., reported to his stockholders that at the beginning of the War the company had felt obliged to decline contracts for certain dredges in prospect, for fear of disappointing buyers as to promised delivery. In general, however, our machinery men find it possible to take care of all regular customers.

Dredging. Speaking of dredges reminds me that in the Kytlim Valley, Russia, where dredges are used to recover both gold and platinum, results continue to be good. R. S. Botsford described for readers of the Press, in February last, the character of the enterprise. There are now three boats at

work, one a Putiloff of 5½ cu. ft., another a Marion 7½ cu. ft., and the third a second-hand Putiloff that has been digging without much success in another part of the estate. I understand that Mr. Botsford has no responsibility for the last-named result. The Marion boat is reported to be moving nearly 5000 cu. yd. per day, at a cost of 62c. per yd., with a recovery of about $2.85 per yard. The Putiloff boat is treating 120 to 150 cu. sagenes—1700 to 2000 cu. yd. per day. As the estate is large and the results are good, it is not unlikely that more boats will be built. In contrast it may be noted that the returns from the Nechi (in Colombia) have not come up to expectations, though there may be good reasons. The first figures issued, covering two weeks ended on November 1, showed that 77,322 cu. yd. dredged has yielded $16,715, equivalent to 21.3c. per cu. yd. The estimate for 90 acres of tested ground, it will be remembered, was 70c. per cu. yd. And it will also be remembered that at the meeting of the company in August the chairman stated that it was expected that the dredge would begin operations September 1. He then estimated that the return for the last two weeks in September would be £10,000. No one experienced in dredging will consider it a serious matter that on a two-weeks run the yield is below the average determined by drilling, any more than he would be especially elated and re-calculate the value of his shares if for such a period the returns were more. It is also to be remembered that it was necessary for the dredge to move across the river from where it had been erected, and to dig a pond in lean ground. An office note added to the report is to the effect that the dredge is still working in ground of medium value, and that it will be a couple of months before it has worked its way through to the rich ground. Incidentally, it may be noted that Nechi is one of the companies that will need to take careful account of the new 'war profit tax,' since all of its income for this year will be excess over that of the year before—it being a new company—and so will be subject to a 50% tax unless the proposed revenue measure be modified. On the whole, and regardless of the value of the ground and the excellence of the dredge and the technical direction, Nechi does not seem likely to pay large profits immediately.

Russian Mines. The Anglo-Russian mining companies are doing well, and there is great activity at all points. Moderate dividends, of course, are the order of the day, for exchange is heavily against bringing money out of the country, and only limited gold shipments are permitted. The Kyshtim even found it advisable to cease export of its rich precipitate and to build a small refinery. R. Gilman Brown, who recently returned from Russia, reports things moving rapidly at the Irtysh and elsewhere. The new zinc smelter, of 480 retorts, will begin to produce about the first of the year, and a whole railroad, rolling-stock, and all, was bought from the Russian government and moved to the mines. The Government is helping the mining companies in every way possible, as the importance of a supply of metals is fully realized. At the Spassky and Atbasar active building of smelter and other works is under way and at the former good production is kept up. E. T. McCarthy was not able, as Mr. Brown was, to buy a complete railroad—I do not know if there were competitive bids—but he did buy a long train, several locomotives, and about 13 miles of track. With this he is moving the new machinery across the steppes by alternately tearing up the rails behind the train and re-laying them in front. The new railroad and port that Russia has built on Kara bay ought to make it possible by spring at least to bring in adequate supplies. The line is actually laid, but not yet ballasted, and those who rode from Chitina to Kennecott (in Alaska) the first season the Copper River line was open, will realize what that means as regards heavy shipments of machinery, for the country is about the same character. In connection with the Copper River line, we learn with interest that the equipment is to be considerably augmented to carry the Kennecott copper ore.

Company Reports. You will have had the Tomboy report and noted the continued success of that excellent property. Purchase of the White Cloud is looked upon here as an excellent stroke of business. The Messina report shows good profits and increased recovery, but a considerable shrinkage of ore reserves. A thorough examination by A. F. Kuehn has been made, and his figures have been adopted by A. B. Emery, who is now manager. The Burma Corporation, by way of contrast, shows a great increase in reserves, and T. J. Hoover estimates that if the great ore-shoot continues another 50 ft., which will bring it to the Tiger adit-level, some 3,000,000 tons of ore will be available. At present the reserve stands at 2,000,000 tons, containing 27% lead, 22.5% zinc, and 25 oz. silver per ton. It will be nine months or a year before the mine and the adit are connected, and for the present more interest attaches to the 250,000 tons of high-grade lead (45%) silver (44 oz.) which is to form the immediate source of income. It is expected that the production will be sufficient to not only pay operating expense but provide all the capital needed for the next year. The Burma board has recently been re-constituted so as to bring to it certain gentlemen formerly connected with railways and Government work in India. The relations of the Corporation to local officials have not been altogether happy, and it is hoped in this way to decrease friction. As an example of how matters have gone, it may be stated that local officials asked about $12.50 per hp.-year bare rental for water-power. At this price it was cheaper to buy Sulzer-Diesel engines in Switzerland and generate electricity from oil, which has been done, though the water-power is thereby wasted. It is unfortunate that in India, as in some other quarters of the earth, the indirect benefits to a community of the development of a large enterprise seem not to be recognized fully. However, the world is hungry for metal, and mining engineers are pre-eminently able to accommodate their work to conditions as they actually exist.

CRIPPLE CREEK, COLORADO

Shaft-Sinking and Treatment-Plants.

The past three weeks have been extremely quiet as far as rich discoveries are concerned. The larger mines have produced the usual quantity of ore. It is considered that November will be the banner month of the district.

Sinking is now in progress at the main shaft of the Elkton Con. company. If the water continues to recede at the present rate a new station will be cut before many months.

The shaft of the Golden Cycle company will be sunk another 25 ft., and then a station will be cut. After this a 50-ft. sump will be excavated. When this is accomplished the total depth will be 2225 feet. This will make the Golden Cycle the deepest in the district.

A new hoisting plant with capacity for hauling from a depth of 2000 ft. has been ordered for the Dillon mine on Battle mountain. In all probability the Dillon shaft will later become the main shaft of the Granite company.

The mill owned by the Isabella Mines Co. has been leased to John C. Klauck for five years. It is understood a straight cyanide process will be used. Both mine and dump rock will be treated. It is hoped to have the mill running at full capacity early in the new year.

After careful experiments conducted over a long time, the Portland company has decided that the low-grade ores of the Cripple Creek district can be successfully treated by oil flotation. The Independence mill at Victor will soon be equipped with machinery for this process.

At a recent meeting of the shareholders of the Dante company it was decided by unanimous vote to extend the charter for another period of 20 years.

The Colburn mill at the Ajax mine is treating 60 to 70 tons of ore daily; this will soon be doubled. Forty sets of lessees are busy in this mine.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

FAIRBANKS

A company has been organized at Fairbanks to mine coal from the Nenana coalfields as soon as the Government railroad is completed, which may take two years. As firewood costs $16 per cord, equivalent to $32 per ton for coal, only rich quartz mines can be worked; but with coal landed at $5 to $6 per ton, many low-grade claims can be developed, as has been discussed in the PRESS by our Fairbanks correspondents.

THE NEW RAILROAD AT ANCHORAGE, ALASKA.

About $50,000 will bring the coal area to the production point, as the seams are exposed.

A steam-shovel, to be driven either by steam, electricity, or gasoline, is to be tried underground in a gravel mine on Fairbanks creek by J. W. Toole and others.

Some of the antimony ore being mined at Fairbanks has been sent to the Chapman Smelting Co., San Francisco, with which the miners are satisfied. A shipment in September amounted to 78 tons of ore, from the Ridgetop and Eagle mines. It averaged respectively 55 to 61% metal, for which the high price of $2.20 for 55% and $2.50 for 60% ore per unit was paid. The total gross amount of the shipment, which was paid for on a spot cash basis, after being received at the smelter, was $10,871.

ARIZONA

COCHISE COUNTY

The 1915 Mining Review issue of *The Bisbee Daily Review* was published on November 21. Besides covering the Warren and other districts of this county, the whole of Arizona is discussed by various writers, summarizing as follows:

"Mining in the entire state of Arizona was never in a healthier condition than it is today. From every district comes the report of progress and development, not mentioning the production of the proved mines. The prospector is being heard from in every part and money is to be had for the development of properties. The manner in which the general public is responding to the demand for money in the Mohave County goldfields is ample proof that one of the greatest mining booms, in the history of the United States, is about to be seen. By the laws of the State of Arizona there can be little or no wildcatting. In this way the investor in the mines that are now being promoted will get at least a run for his money. There has always been the complaint that the promoters got all of the money, and little of it went into the ground. The charge has been justified in a number of cases. At the present time, however, the corporation commission is very closely scrutinizing the application to sell stock, and the margin of promotion costs has been cut to a minimum, assuring that the money subscribed or a great proportion of it, will be expended for legitimate purposes."

GILA COUNTY

Work done on the 22 claims of the Powers Gulch Development Co. along the Gila and Pinal counties boundary, totals nearly 2000 ft., down to 176 ft. depth, and the lessee, U. Jackson, has opened good tungsten ore. A shipment of 831 lb. sold to the Primos Chemical Co. realized at the rate of $1346 per ton. This ore was not dressed. The property also contains good copper ore.

Another blast-furnace, No. 3, was blown-in at the Old Dominion smelter on November 20. The mill is treating 700 tons daily. No. 18 level has been drained, and the electric pumps are at work.

At the Inspiration there has been a general clean-up of the debris on the surface and underground. The miners' change-house is nearly ready. The coarse-crushing plant is complete. Nine units are working in the mill.

A power-plant to cost $50,000 is contemplated by the Arizona Commercial company at Globe. The monthly output is 400,000 lb. copper, yielding a profit of $20,000.

GREENLEE COUNTY

The Federal government investigation into the strike at Clifton is now under way. It is reported that strike-breakers are being brought into the district, and trouble is expected.

MOHAVE COUNTY

At 900 ft. in the Gold Road mine, a large orebody has been opened on the foot-wall. The last weekly shipment of bullion was worth $19,000.

The Copper Giant mine, eight miles east of Hackberry, is sending 40 tons of rich ore daily to the United Verde smelter at Clarkdale; this will shortly be increased to 100 tons. Development at 500 ft. has been most satisfactory. W. Neagle is in charge.

The Iowa claims have been sold to E. M. Coplen and H. A. Cole of Los Angeles for $150,000. The mine is opening in splendid style. F. W. Dryden of the Boundary Cone company was connected with the transaction.

A large deposit of disseminated copper ore is said to have been proved at Mineral Park, in the Cerbat range, Wallapai district; O. A. Turner is interested.

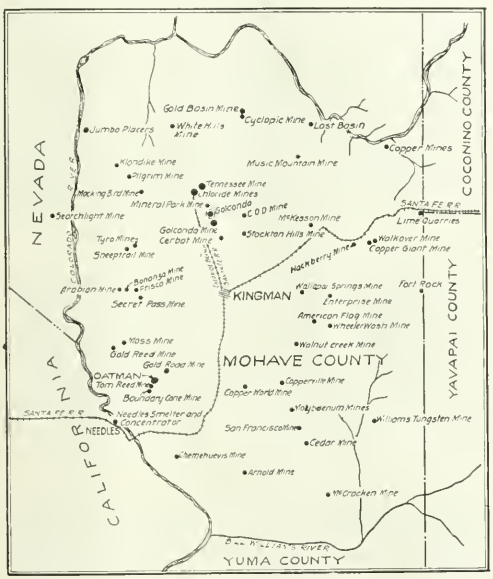
At 505 ft. in the United Western a station and sump have been cut.

Sinking to about 500 ft. is under way at the Lexington-Arizona, Nellie, Lucky Boy, Lazy Boy, Oatman Southern, Goldroad Capote, Lost Treasure, and United Southern mines.

In the Cedar Valley district, 56 miles south-east of Kingman, the Arizona Venture Corporation is to enlarge its operations. The ores contain zinc, gold, and silver. In the Waldron claims lenzite crystals, used in wireless telegraphy, are found. A recent shipment contained 405 crystals, valued at from $4 to $25 each.

The Putney claims have been bought by J. Parke Channing, G. W. Long, and J. L. McIver.

The Oatman district was recently inspected by J. K. Turner of Goldfield, Nevada, and he made the following remarks in part: "I am very much impressed with my observations in the camps of Mohave county, which I have visited during the last few days. This region is the cynosure of all eyes of the mining world, and I consider its future as particularly bright. The activity at Oatman is truly astounding, as is also the extensive programs of operations outlined by no less than 30 companies, which appear to be well financed and prepared for deep work. The United Eastern is a remarkable property, and I have no doubt that others similar to it will be developed in the district. * * * One of the notable features of the present activity throughout Mohave county is the presence of such a large number of former Goldfield people. * * * In addition to Oatman, I have visited the Maynard district and inspected the property of the Arizona Tellurium Mines Co., which, I found, has a wonderful showing for the amount of development accomplished. The formation there is granite, intruded with porphyry dikes. * * * I have also visited the Stockton Hill portion of the Cerbat range, but made only superficial inspection of several properties. The conditions prevailing there are pleasing. I have been commissioned to examine several properties in this section for prospective buyers and upon my return here in a few weeks, will make a more complete study of conditions throughout Mohave county."



MAP SHOWING MINES IN MOHAVE COUNTY, ARIZONA.

The Ajo railroad will be finished to Ajo wells early in January. Rails have been laid to Black Gap, 18 miles south of Gila. The country between Gila and Ajo is practically a desert. The water supply for Ajo has been developed in an extensive 'wash,' seven miles north of the New Cornelia mine of the Calumet & Arizona company, from where it is to be pumped through a 10-in. pipe. Exploration is still under way at this great property. A 40-ton leaching-plant is producing some copper from the experiments under way. A 3% sulphuric acid dissolves the copper, which is afterwards electrically precipitated. Employees at Ajo are mostly Mexicans; the population is 1000.

Pima County

Yavapai County

The United Verde Extension mine is producing 40 tons of ore per day, employing 80 men. Results on No. 14 level are very satisfactory.

(Special Correspondence.)—The Sunflower Cinnabar Mining Co. has made an unexpected discovery of quicksilver ore in the Packover claim. This mine is situated in the Mazatzal range, about 75 miles north-east of Phoenix.

The Randolph-Gemmill Development Co. at Crown King is reported to be treating successfully the refractory ores of that district, and is milling 100 tons daily of the Crown King dump, on which a lease is held. The company will enlarge the plant to treat custom ore.

Hübnerite has been found by some Prescott people in the Eureka district, on claims adjoining the holdings of Lawler, Wood, and Conner, who have already made shipments of this ore.

Prescott, November 27.

ARKANSAS

Benton County

The Arkansas zinc and lead region was recently visited by J. P. Dunlop of the U. S. Geological Survey. He was impressed with its possibilities, and estimates an increase of 400% in output over last year. Prospecting and mining are done at low cost on account of the hilly nature of the ground. Most of the mines are dry.

From the Red Cloud mine near Rush, an important development is reported at 1100 ft. in an adit.

CALIFORNIA

Amador County

The South Eureka company has resumed mining at its Oneida property, nearby. Unwatering is to be commenced, and then the opening of the known orebodies. W. J. Bryant is in charge under W. H. Schmal, the superintendent of the company.

The Rhetta mine, four miles north of Plymouth, is to be re-opened by B. C. Clark, who will install machinery at once.

Renewed activity is reported from the old Charleston district.

Inyo County

The Wilshire Bishop Creek mine is closed again until the spring; only a watchman remains. Results were fairly satisfactory. Mining was done above the 300-ft. level. Up to October 1 the output for the season was 5000 tons valued at $11.40 per ton. Recovery is not as good as desired, and the cyanide-plant may be converted into one using flotation.

Nevada County

Owing to caving there has been a good deal of trouble in unwatering the Union mine at Nevada City, under bond to San Francisco people.

Plumas County

A stamp-mill has been erected at the New York mine, owned partly by Mrs. J. F. Peattie of Chico, Butte county. A large quantity of ore is ready. More machinery will be added in the spring.

San Bernardino County

(Special Correspondence.)—All parts of the Atolia district are busy. The main interest is development of new veins and pockets, along the Piute, Paradox, Papoose, and Churchill veins, which is being pushed with vigor by the Atolia company. The management is preparing for an increased production, and contemplates employing at least 150 additional men. To cope with this extra force 85 additional 10 by 12-ft. tents, with board floors and walls, are being built at the north side of the mill. The place is now a large tent city. Additional tools and steel have been ordered, and there is every indication that machine-drills will be used on the lower levels.

On the 150-ft. level of the Papoose, near its east end, a lessee named Harry Hughes, has high-grade ore. Seventeen men are working two shifts.

At Churchill No. 1, the main shaft is down over 1000 ft., with good ore at the bottom.

On the Spanish lease a new hoist and head-frame are being erected, with ore-bins, engine-house, and blacksmith-shop. The orebody continues good, and is apparently the same vein that has been cut over 1000 ft. east in the Lipp and Brock lease, on the Skylark claim. This lease has been a great producer of scheelite of exceptional value. A carload of concentrate was shipped East last week valued at $60,000. Besides this, 13 tons was purchased by the Atolia company at a high price, said to be over $40 per unit of 60% grade.

Carl Mangel, who picked up 650 lb. of float in a drift at the bottom of his shaft, recently found the vein from which it came. It is said to be a large low-grade lode with alternate streaks of rich ore.

New and promising tungsten developments are reported 2½ miles south of Atolia on the old Kramer road. Stringers of quartz containing a fair percentage of tungsten have been found near the surface in granite. It has been termed 'the orange-pickers find.'

Miners are continually arriving here, and this part of San Bernardino and Kern counties appears attractive to lessees and prospectors, all of whom are apparently prosperous. Many outfits are moving about with automobiles especially equipped for camp life.

Traveling auto-stores that sell groceries, meat, fruit, and produce, have made their appearance, doing a thriving business. One of these last week brought the Los Angeles dailies of the same day to Atolia, beating the train deliveries by over four hours.

A tri-weekly auto-stage from Randsburg to Los Angeles, run by W. Eaton, carries passengers and fast freight between all points en route, *via* Atolia and Lancaster. The trip is made in seven hours, and when desired the route is varied by way of San Bernardino and Kramer, both coming and going.

A few investors are becoming interested, but the lucky ones generally seem content to work their own properties and sell the high grade at $1.50 to $2 per lb. to local buyers.

Atolia, November 25.

Shasta County

The Balaklala mine is shipping 9000 tons of ore per month to the smelter at Kennett. One hundred and twenty men are employed.

Deeper work in the Greenhorn copper mine is very encouraging. Old workings have been connected. M. E. Dittmar is manager.

Siskiyou County

On account of the snow in the Salmon River district most of the miners are closing for the winter; these include such producers as the Black Bear, Cub Bear, Highland, Homestake, and Trail Creek.

Stanislaus County

A narrow-gauge line is being surveyed from Patterson to the magnesite mines, a distance of 22 miles.

Trinity County

Work has been resumed at the old Mammoth claims on Bullychoop mountain, near Douglas City, by D. C. Dedrick. Some good ore is ready for the small battery on the property.

On November 25 two inches of rain fell at Weaverville, and 30 in. of snow at the Globe mine near Dedrick, also 24 in. of snow on the divide between French Gulch and Deadwood.

Tuolumne County

(Special Correspondence.)—The Black Warrior mine, situated on the east belt, is one of the most promising properties to be re-opened in this vicinity in the past year. The property is being developed by an adit, which is in 300 ft. The vein is large and the ore free milling. A two-stamp mill was recently erected and is operating at full capacity. The Black Warrior was located in 1856 and worked by the late E. Westinghouse.

The Experimental mine, in Experimental gulch, above the town of Columbia, is yielding good returns to its owners. Conlin Bros. A 2800-ft. adit has been driven to cut the ore-shoot that was very rich on the surface in the early days. The adit has some distance to go before this shoot is cut, but a rich orebody has been opened and is being milled. Three more stamps are being added to the original two, and the plant will be in operation within another week. For two months preceding the closing of the mill, the output was over $4000 per month.

Sonora, November 27.

COLORADO

Boulder County

During October the Chamberlain ore-sampler at Boulder handled over 600 tons of tungsten ore, compared with 248 tons of gold, silver, copper, and lead ore. The average value of tungsten ore exceeds $300 per ton, making $180,000, while the average value of the gold and silver ore was only $35 per ton, with less than half the quantity of tungsten ore, netting the producers only $8750. Thus it will be seen that there is over double the tonnage of tungsten ores marketed in Boulder over gold and silver, and that the miners receive about twenty-five times as much for tungsten ores as for the other minerals mined.

Clear Creek County

Chicago and St. Louis people, headed by L. W. Shaffer, have obtained control of the McClelland Tunnel Co. owned by the United Freeland Development & Tunnel Co. The sum of $150,000 changed hands, and $100,000 has been allotted for working capital. The area comprises 106 patented claims, mill-sites, and three tunnel-sites, with a total length of 18,000 ft. The McClelland tunnel is in 7149 ft., and will be extended 3000 feet. The Freeland mine has a production of $5,000,000 since 1869. A large mill is proposed.

Gilpin County

The Polar Star mill, at the mouth of Chase gulch, Black Hawk, has been secured by the Bates Leasing Co. The plant is being overhauled, Wilfley or Card tables to be installed, and probably a flotation-plant.

High-grade ore continues to come from the Pittsburg mine in lower Russell gulch; it returns up to 9 oz. gold, 9.4 oz. silver, and 17.6% copper.

Lake County (Leadville)

At the Penrose shaft of the Down Town area the water is down to 687 ft. Large quantities of water from old stopes tax the pumps to their limit. The heavy work of clearing and retimbering the 600-ft. station is finished.

Steady progress is reported from the Anderson adit near Birdseye.

The new leasing company at the Big Four mine on Breece hill has commenced work, with John Cortellini in charge. The lessees feel confident of good results.

San Juan County

A flotation-plant has been installed at the Gold King mill at Silverton, and treatment is in full swing in charge of Louis O. Bastian.

A 500-ft. contract has been completed at the Columbus mine at Animas Forks, and a similar distance is to be driven in the Elk company's mine, 3½ miles from Silverton.

Teller County (Cripple Creek)

At 1300 ft. in the Gold Sovereign mine the shoot has been opened 60 ft. The core is very rich, and is being sacked.

Recent assays at the north and south end, over 18 in. in each, gave 11.48 and 266.5 oz. per ton.

At the Jerry Johnson the Cripple Creek Deep Leasing Co. has opened 60 ft. of ore at 850 ft. depth. More men are to be employed.

The Cresson continues to produce rich ore, and during the past 30 days eight cars of ore were valued at $380,500.

At the Independence mill a large sampler is to be constructed, while plans are complete for the installation of a flotation-plant in place of the present cyanide-plant. Ball-mills will supplement the Chilean mills.

IDAHO

According to an estimate of the State mine inspector, Robert N. Bell, the mineral output of Idaho will be $30,000,000 in 1915, an increase of $5,000,000 over that of last year.

Clearwater County

The holdings of the Ozark Mining & Milling Co., consisting of the Wild Rose group of 14 claims and the Ozark group of 7 claims, three miles east of Pierce, abandoned for the last three years, have been located by R. H. Bailey, mining engineer, of Spokane. Mr. Bailey announced this week that development of the properties would be begun next spring, when a compressor and hoist will be installed. A lower adit was driven several years ago a distance of 1250 ft. in the Wild Rose area, and a raise opened good ore. Water stopped work in the Ozark but $10 to $15 ore was left in the face.

Shoshone County (Coeur d'Alene)

The Alameda *v.* Success apex-suit is attracting a good deal of interest at Wallace, but progress is slow. Maps and models are used by both sides.

A good shoot has been cut in the Surprise mine, nine miles from Kellogg. The new 150-ton mill is at work. The concentrates assay 40% zinc, 70% lead, and 20 oz. silver per ton. Motor-trucks haul the product to the railway at Kellogg.

The Federal Mining & Smelting Co. has declared $1 per share on the preference shares, equal to $120,000, making $480,000 for the year. Common shares have received nothing since January, 1909.

Development at the Sunset mine, on Sunset peak, has opened a good deal of zinc and lead ore. To allow of larger operations, a new hoist, compressor, drills, etc., motor driven, have been ordered.

The Hecla company at Burke has declared a dividend of 7c. per share, equal to $70,000; this makes $465,000 for the current year, and $3,655,000 to date.

The Colonial Mining & Milling Co., operating the Little Pittsburg on Pine creek, has secured a contract calling for one car daily after January 10, according to J. D. Beebe of Wallace, president and manager of the newly organized company. A 250-ton concentrator is being erected on the Colonial ground, one section being now in place. A tramway, 5178 ft. long, is also being constructed to convey ore from the mine to the mill, from 40 to 50 men being employed in order to rush the work. A sorting-plant is being erected for handling the high-grade ore. No. 2 adit has been started, and should cut the vein at a depth of 600 ft., in 450 ft. No. 1 adit cuts the vein 400 ft. below the surface, and at this point there is an ore-shoot 20 ft. wide, containing zinc, lead, and silver. After sorting out the rich ore, it should concentrate to 45% zinc.

MICHIGAN

The Copper Country

Copper shipped from Lake Superior mines this season by the Mutual Transport vessels will be 100,000,000 lb., fully 30,000,000 lb. above the total of last season. Two steamers were loading 3000 tons each last week.

Further diamond-drilling at the White Pine has proved the extension of the copper-bearing sandstone. It is said that a larger mill will be erected next year about four miles from the mine.

Good progress is reported from the White Pine Extension. A caterpillar tractor is hauling supplies, resulting in reduced cost.

MISSOURI

Jasper County

For over $100,000 the Knight Investment Co. of Utah secured the Lucky Tiger and Black Hawk mines at Neck City last week. They were owned by G. L. Cole, are good properties, and are equipped with a 250-ton mill each.

The output of the Missouri-Kansas-Oklahoma district during the week ended November 20 was as follows: blende, 6301 tons; calamine, 1179 tons; and lead, 884 tons, averaging $100.77, $66.11, and $62.63 per ton respectively. The total value was $770,368, and for 47 weeks, $22,018,220.

On account of the continued high prices of ores an increase of wages is expected in the district for December.

The Home Talent mine at Duenweg has produced calamine worth over $400,000, with plenty more ore ready. Calamine mines do not last long as a rule.

MONTANA

Cascade County

The Montana Power Co. has completed its Volta hydro-electric plant at Big Falls, 11 miles from Great Falls on the Missouri river. This work occupied three years. The plant includes four 15,000-hp., and two 800-hp. generators. Two more large units are to be installed. The power is used for mines, mills, and smelters, in Montana and Idaho, electric railways, and town lighting.

Silverbow County

The October output of the Butte & Superior mine was as follows:

Ore treated, tons	43,092
Zinc concentrate, tons	10,473
Extraction, per cent	93
Value of product per ton	$79.59

When the East Butte company's Pittsmont shaft was sunk to 1830 ft. from 1500 ft. a very wet and heavy fault was cut, hindering work. This is now better, and sinking will soon be resumed to 2100 ft. Ore is being mined between 600 and 1500 ft. The re-modeled smelter has a capacity of 900 tons of ore per day. Two units of the flotation-plant will be ready early in 1916.

NEVADA

Esmeralda County

The final report of the Goldfield Consolidated for October shows that the net profit was $98,376 from 36,500 tons of ore. Costs were $4.40 per ton. Development totaled 2760 ft. at $4.51 per foot. Lessees produced 119 dry tons of ore of a gross value of $3995, from which the company received $1998, less the cost of transportation and milling.

At a depth of 428 ft. the first coal seam has been cut in the new shaft of the Darms Coal Mining Co. at Coaldale. It is small, but of good quality.

Humboldt County

The Rochester Mines Co. contemplates additions to its mill, and has secured further water-rights in Relief and Buffalo canyons.

The new 100-ton mill of the Nevada Packard Mines Co. commenced work on December 1. It was constructed by K. Freitag. Six men is the only labor required.

The Nenzel Crown Point Mining Co. has resumed work; its property adjoins that of the Rochester Mines Co.

The first deep work at Willard which is to prove or otherwise that the veins persist to depth is about to be undertaken at the Kaiser lease on the Sheepherder's Dream. B. T. Godfrey of San Francisco has bought-in on the lease, and is to erect a hoist for the new work. The last discoveries in the group indicate that the old high-grade vein has been recovered, and it is asserted that there are several thousand dollars in sight at the present time.

LYON COUNTY

The Nevada-Douglas new leaching-plant will soon be working at full capacity. A large supply of ore is waiting at the mine, also custom ore. High-grade copper ore is being shipped to Utah, a contract for 1000 tons being arranged with the International Smelting Co. at Tooele.

MINERAL COUNTY

Claim-jumpers at 25 miles north-east of Mina were recently decided against by the Court at Hawthorne. They had jumped part of the ground of J. P. Nelson, but it was held by the Court that his monuments prevailed over the call in his notice, although his measurements were incorrect. Work is to be resumed on the property.

NYE COUNTY

Tonopah mines last week produced 9951 tons of ore worth $205,078. The rise in the price of silver has cheered up everybody. Satisfactory developments are reported from several mines. On January 2 the Belmont company will pay 12½c. per share.

STOREY COUNTY

Prospects at the Union Con. and Sierra Nevada mines at Virginia City are very encouraging. At 100 ft. in the joint raise from 2500 to 2400 ft. an east cross-cut has opened $50 ore.——The Mexican mill treated 168 tons of $25.63 custom ore. ——The United Comstock Pumping Association has repaired 302 ft. of the 2700-ft. level. The pumps at 2000, 2300, and 2500 ft. are working well.

TEXAS

CULBERSON COUNTY

(Special Correspondence.)—Mining in western Texas is busier than at any previous time, there being considerable preparation in opening mines and extracting ore.

The Mineral Milling Co. has been organized with a capital of $50,000 to operate in the Hazel district, near here. The incorporators are Henry M. Sutton, Walter L. Steele, and Edwin G. Steele.

The Culco Mining Co., which was recently organized with a capital of $5000 with its head office at Dallas, will start development in the Van Horn district. The incorporators are A. C. Horn, L. E. Dougherty, Jesse Williamson, and Daniel Byrnes, all of Dallas.

Van Horn, November 27.

UTAH

BEAVER COUNTY

A considerable amount of development continues at Fortuna. The Davis lease has crushed 30 tons of ore worth from $30 to $50 per ton. Properties are being taken under option.

The U. S. S. R. & M. Co. has purchased the Lumry and Moore claims for $150,000, 10% being paid down and the balance spread over 18 months. The company also took over the Davis lease.

BOXELDER COUNTY

Three miles north of Brigham, ore assaying up to 68% antimony, 25% sulphur, 2.9 oz. silver, and 0.3% arsenic has been opened. A sample weighing 110 lb. has been on view at Ogden.

JUAB COUNTY

Tintic mines shipped 139 cars of ore last week.

A lessee at the Chief Consolidated has opened high-grade gold ore.

On the 1000-ft. level of the Lower Mammoth, ore assaying 30 to 40 oz. silver and 4% copper has been cut. It is four feet wide. Zinc ore is being extracted from the 1400, 1500, and 1700-ft. levels.

A carload of ore from a new shoot in the Yankee Consolidated assayed about 180 oz. silver, $8 to $10 gold, and 5% lead.

From the 1600-ft. level of the Mammoth 2-oz. gold ore is being shipped. A large body of copper ore exists at 600 ft. The mine generally is in splendid condition. Earl McIntyre is superintendent.

On December 20 the Eagle & Blue Bell company will distribute 5c. per share, equal to $44,657, making $133,972 for 1915. The monthly output is 3000 tons of $30 ore. A new 250-hp. electric hoist is being made in the East.

SUMMIT COUNTY

Park City mines shipped 1516 tons of ore last week.

On December 21 the Silver King Consolidated will pay 10c. per share, or $63,750, making $252,500 for 1915.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Quilp Gold Mining Co. has brought suit in the Superior Court in and for Ferry county against the Republic Mines Corporation, to enforce the trustee in bankruptcy of the latter to deed the ground disputed in a former suit, which was compromised by contract of settlement on May 2, 1913. The hearing of the case was continued from November 18 to December 17, on account of illness of the trustee in bankruptcy.

Republic, November 19.

OKANOGAN COUNTY

(Special Correspondence.)—The manager of the Arlington mine, Ernest Stoolfire, will ship 50 carloads of ore this winter. Thirty men are employed on day and night shifts.

Marshall and Roe of Seattle, who bought tungsten claims near Cathedral peak, a short distance from the international boundary, have been developing the property, and now announce that they will build a wagon-road and erect a concentrating-plant. At present the mines are almost inaccessible. The concentrate is mostly wolframite, assaying as high as 73% tungstic acid.

In the Chesaw district the Molson Gold Mining Co. is applying for patent to the Peerless placer ground.——At the Gold Ax mine a night shift has been started, and from shaft-sinking, ore is being extracted and shipped to the smelter.——In the Enterprise mine an adit is in 120 ft., and connected with a shaft at a depth of 75 ft. A drift is being driven on the vein, to be continued to No. 2 shaft, several hundred feet distant. ——The Caribou mine is under active development and producing low-grade copper ore.——The Iron Mask is showing some fine copper ore.——Good gold-bearing ore is being developed in the Roebuck and North Star claims.

A company has been formed by a number of business men in the town of Twisp to develop placer ground five miles from the town, on which claims have been staked along the bottom of Twisp river. The gravel beds are thought to extend several miles along the river.

The Stewart Calvert Co. of Seattle, is shipping a large quantity of epsom-salts (magnesium sulphate) to New York, Philadelphia, Chicago, and Pittsburg, said to be 98% chemically pure, from a lake owned by the company near Oroville. Freight is $10 per ton to Chicago, and $15 per ton to New York, Philadelphia, and Pittsburg. The shipments are reported to average 250 tons per day from Oroville, over the Great Northern railway. The supply is said to be very large.

Republic, November 19.

STEVENS COUNTY

Northport, where the smelter is being re-built, is very busy, there being over 250 men employed. One large job is a three-mile flume and tunnel for hydro-electric power. The Day interests, connected with this smelter, have purchased the Pennsylvania Smelting Co.'s refinery at Carnegie, Pennsylvania, to receive products from Northport.

CANADA

MANITOBA

(Special Correspondence.)—Canada has another gold rush, and prospectors who have been locating claims in the Rice Lake district, 100 miles north of Winnipeg for the past year, have brought in samples which seem to indicate that the locality is rich in minerals. Claims are also being staked in the Gold Lake district, 50 miles north of Rice lake.

The strata extends from Cumberland lake, north-west of La Pas, south-easterly into the Rainy River district. There is a gneissic formation, with seams of from one to six inches wide, showing tracings of gold, iron, barite, with some copper and silver. La Pas is a town of about 3000 inhabitants, situated on about the only available crossing of the Saskatchewan river for 100 miles on either side. The town is on the south side of the river, the Indian reserve on the north. It is difficult to reach, as there are only three trains a week on the Canadian Northern to this point. Another means of reaching the Rice Lake district is by a small steamer from Winnipeg to the mouth of the Monogotogan river, which flows into Lake Winnipeg, 100 miles from Winnipeg; from there it is possible to ascend the river in canoes 50 miles to Ratroot lake, and then overland, and from there portaging over rough country, a distance of 12 miles to Rice lake, thus making the transportation of machinery extremely difficult, even that of a portable nature.

The Beaver Lake goldfield, which also is being developed in a small degree, but which is being thoroughly prospected, is north-west of La Pas. Practically all of the claims filed in the district have been staked for speculative purposes. Several prospectors and mining engineers from Boston and Minneapolis have gone to the new field, and on returning were reticent as to the prospects. The Provincial government is to make an effort to obtain the mineral rights from the Dominion government, which owns all the minerals in the Province of Manitoba. According to the records, Manitoba has received upward of $4000 in fees for recording the 746 claims in good standing in the Rice and Gold Lake districts. These records show that $260,000 has already been expended there, 20% of which has been for transportation.

Winnipeg, November 25.

YUKON

In the Mayo district a good deal of development is reported, and the next season is expected to be a good one for placer and quartz mining.

MEXICO

The National Railways of Mexico report as follows for the year ended June 30, 1915:

	1914.	1913.	1912.
Total operating revenue..	₱34,273,341	₱57,370,282	₱61,987,108
Net	3,454,363	21,299,478	21,888,033
Deficit after charges.....	28,835,624	687,383*	2,360,347*
Preferred dividends	.....	1,153,316	2,306,632
Deficit	28,835,624	465,933*	53,715*
Profit and loss deficit....	28,736,661	98,963*	567,052*

*Surplus.

SONORA

On November 23 the first train for several weeks left Naco for Cananea loaded with supplies of all kinds for people and mines. Not much damage has been done to the town. It is expected that mining and smelting will be resumed before long.

PERSONAL

S. A. IONIDES is here from Denver.

RICHARD A. PARKER has gone to Boston.

W. DEL. BENEDICT has returned to New York.

FRANK L. SIZER has gone to Tonopah, Nevada.

THOS. H. LEGGETT was at Los Angeles this week.

FRED T. GREENE, of Butte, is at the Hotel Oakland.

BEN. B. LAWRENCE is on his way back to New York.

ARTHUR W. JENKS has returned from British Columbia.

WILLIAM B. DENNIS, of Carlton, Oregon, is in San Francisco.

H. W. GEPP left San Francisco for New York on November 26.

E. E. PRICE, from Salt Lake City, is at Sonora, in Tuolumne county.

DAVID J. ARGALL passed through San Francisco on his return to San Diego.

ROBERT M. BETTS, manager for the Cornucopia Mines Co., of Oregon, is here.

HENNEN JENNINGS has been appointed a consulting engineer to the U. S. Bureau of Mines.

STANLY A. EASTON, manager of the Bunker Hill & Sullivan mine, Idaho, was here during the week.

W. J. LAKELAND, of the Burma Mines, Ltd., has arrived here from Burma on a journey of technical observation.

ALTON DICKERMAN, geologist to the Allouez copper mine, in Michigan, is taking a holiday in southern California.

L. D. RICKETTS, W. D. THORNTON, A. C. JAMES, T. M. SCHUMACHER, and WALTER DOUGLAS were recently at Globe, Arizona.

J. G. BERRYHILL, vice-president of the Nevada-Douglas Consolidated Copper Co., was at Ludwig last week inspecting the new plant.

P. D. BURTT has been examining properties at Manhattan, Nevada, and has returned to the Nevada Packard mine near Rochester.

L. C. DE LA MARLIÈRE, general manager for the Andrada Mines, Ltd., in Mozambique, has returned to France, to serve his country.

CORNELIUS CUDDIHY, smelter foreman for the Anaconda, is in the Copper Country of Michigan to visit the Calumet & Hecla smelters.

W. R. RUST has severed his long connection with the Tacoma smelter and resigned the presidency of the company controlling that A. S. & R. plant.

SUMNER S. SMITH, Federal mine inspector in Alaska, has been at Valdez with W. MALONEY, the Territorial inspector, visiting the Ellamar copper mines.

PIERRE BOUERY, for 15 years manager of the La Grange placer mine, Trinity county, has been appointed manager for the Valdez Creek Placer Mines in Alaska.

D. D. HOMER sailed on the *Newport* from San Francisco on October 23 for La Union, San Salvador, to serve as assistant manager at the Divisadero mine of Charles Butters & Co.

JAMES FORGIE, consulting engineer of New York, has been awarded the Telford gold medal by the Institution of Civil Engineers (Great Britain) in recognition of his paper on 'The Laxaxalpam Aqueduct Tunnels in Mexico,' and of the achievement in engineering that was the subject of the paper.

Obituary

ORVILLE A. DERBY, geologist to the Government of Brazil, committed suicide at Rio de Janeiro on November 27.

FREDERICK W. DODGE, president of the F. W. Dodge Co., publisher of the Dodge Report Service, Architectural Record, Record and Guide, Sweet's Catalogue, and others, died recently at his home at Manhattan, New York, at the age of 51. He was born at Melrose, Massachusetts.

THE METAL MARKET

METAL PRICES.

San Francisco, December 1.

	Cents per pound.
Antimony	40
Electrolytic copper	20.75
Pig lead	5.50— 5.70
Quicksilver (per flask)	$105
Spelter	21
Tin	43
Zinc-dust, 100-kg. zinc-lined cases	35

ORE PRICES

San Francisco, December 1.

Antimony: 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica per ton	12
Magnesite: plastic, free from iron and lime, calcined, per ton	55
Magnesite: refractory, up to 5% iron, calcined, per ton	30-35
Manganese, 50% metal, 8% silica, per ton	12
Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot	$35—40

New York, November 26

Antimony: per unit, $2.40.

Tungsten: 60%, $45 for shipment this year, and $34 for any time in 1916.

Manganese: 44c. per unit at Rio de Janiero, and 46c. in India.

Molybdenite: 90% MoS_2, per pound, $1.50.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 2.—Copper is quiet, the demand being satisfied; lead is firm but quiet; there are no buyers for zinc and the market is falling steadily.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Nov. 25	Holiday	Oct. 20	49.53
" 26	56.00	" 27	48.91
" 27	56.50	Nov. 3	49.37

June	56.43	49.03	Dec.	49.27	....

Since the rapid advance of last week silver has been a trifle weaker. One reason for the rise is that stocks in London were estimated to be 15,000,000 oz., whereas on November 19 they were only 9,000,000 oz. There is a continuance of demand for English and European coinage purposes. The strength of the market lies in this demand. A. S. & R. Co. stocks are low.

China is an uncertain factor, being a seller and buyer on the same day.

COPPER

Prices of electrolytic in New York, in cents per pound.

The National Conduit & Cable Co. considers the copper situation stable, but if 18.50c. is to have a good foundation there must be a steady and large consumption; any undue inflation is risky.

October returns were as follows: Chino, 6,319,194; Nevada Con., 5,880,082; Ray, 6,072,497; and Utah Copper, 16,004,607 pounds.

Dividends are $1.50 and 50c. by the Old Dominion, 50c. and 50c. by the Shattuck-Arizona, and $3 (quarter) by the Quincy.

Exports during the week ended November 13 totaled 18,874,973 lb., and imports, 5,623,013 pounds.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

On December 4 the Bunker Hill & Sullivan pays dividends No. 219 and 220, totaling $163,500; this makes $16,773,000 to date.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Date.	Week ending		
Nov. 4	97.50	Nov. 17	100.00
" 11	100.00	" 24	105.00
		Dec. 1	105.00

May	32.29	39.28	Nov.	33.51	39.50
June	30.72	40.26	Dec.	33.60	....

Tin is easy at 39 to 39.50 cents.

The A. S. & R. plant at Perth Amboy will be ready January 1 to receive Bolivian 'barilla' and Alaskan concentrate. Capacity of 750 tons metal per month will be 1200 tons later on.

Eastern Metal Market

New York, November 26.

Indications point to a period of quiet in most of the metals. In copper an extremely heavy demand has been practically appeased, at least so far as domestic purchasers are concerned. Spelter has been active, but the high prices cannot attract business, and purchases are made only under compulsion. Lead, though steady, is quieter and the purely domestic demand is not what it should be. Buyers are distrustful of the tin market, and for a week they have been inactive. The London market is uniformly strong and this, of course, acts as a sustaining influence on the American market in general. Spot antimony is scarce and strong at 40c. Aluminum holds to its high level. Galvanized sheets and sheet-zinc are higher.

Practically no orders for shrapnel or high-explosive shells are now pending in the United States, although in Canada such orders continue to be doled out. The makers of metal-working machinery are still subject to a heavy war demand—although England is buying less—while orders from the industrial fields are on the increase. Ability to make deliveries alone regulates machinery sales. The steel trade continues to receive orders at a pace with which it cannot begin to keep up. For shell-rounds, up to 4c. per lb. has been paid. It is difficult to keep posted on the quotations of finished steel products, so rapidly do they advance. Shapes and bars are quoted at 1.70c., Pittsburg, plates at 1.90c., but for these and other products premiums are willingly paid. One result of the mounting prices is the withdrawal by the Pennsylvania Railroad of its inquiry for 11,000 freight-cars, and this despite the fact that the Eastern railroads are doing a business the equal of which has seldom been experienced before.

COPPER

Since Tuesday of this week when the quotation for electrolytic went to 20c., 30 days, delivered, or 19.87½c., cash, New York, copper buying has been less active, and there are signs that the big buying movement of the last two weeks is on the wane. That buying should be tapering off is something entirely to be expected. It must come to an end in the natural course of events, and that the time is almost ripe for such a cessation is indicated by the fact that some consumers have closed orders for deliveries of electrolytic running ahead to next June. The producers have booked a volume of orders that places them in a comfortable position. As heretofore stated, the buying began with Europe taking the metal, but in the last few days domestic consumers have been very active, and copper has been sold for a great variety of uses. The wire-mills were notable purchasers. The market is strong at present, and there does not appear to be any valid reason for any substantial decline in prices. Second-hands and some of the smaller producers may attempt to coax business with offerings of the concessions, but the maintenance of prices is as much to their interest as to that of other sellers. With the business they have taken the producers can afford to rest easy for a time; 'sit tight' as it were, an attitude which supports the market. The strength of the foreign market also will be a sustaining influence. Electrolytic was quoted on November 24 in London at £98. Not all of the recent inquiry is satisfied, though the bulk of it has been cared for. The price of Lake copper is nominal at about the same level as electrolytic, a condition brought about by the withdrawal of Lake quotations. Makers of the better grades are comfortably sold up. Leading producers of sheet-copper are not issuing any open quotations, but the base price is about 25c. Exports of copper, from the 1st to 26th totaled 18,433 tons.

ZINC

Steadily advancing prices caused a good-sized amount of buying in the past few days on the part of those who had overstayed the market, and who had contracts which demanded spelter. The resultant activity sent quotations higher still, and on November 23 they were 19c., New York, and 18.75c., St. Louis, for prompt metal. December deliveries were to be had early this week at about 18.25c., St. Louis, and first quarter at 17 to 17.25c. Brass-mill special was quoted around 21c., and the mills engaged on war orders have continued to call for it. The London market has had a strong influence on the domestic situation. The quotation at London on the 26th was £105 for spot-metal, of which Henry R. Merton & Co., Ltd., under date of November 5, said: "Quotations have been marked up day by day, and early material is very scarce indeed. Business in the galvanizing industry has been going from bad to worse, but the consumption there is negligible compared with the quantities of metal required for war purposes." The London market in futures has been erratic, going up £7 one day and losing £5 the next. There, as here, consumers do not feel warranted in buying heavily into the future, even though the quotations for forward deliveries are relatively low as compared with those for prompt. The domestic market became easier on the 24th, and prompt metal was to be had at 18.75c., New York, and 18.50c., St. Louis. Exports have been heavy, amounting from the 1st to 26th to 7716 tons. The price of sheet-zinc, carload lots, f.o.b. mill, on November 26 was 22c. Only about half of the galvanized-sheet capacity of the country is in operation, though the quotations for No. 28 galvanized range from 4.50 to 4.75c. Practically all prices of metal products are subject to immediate acceptance.

LEAD

For some days the domestic demand has been only moderate, at best, but the price at New York has been firm at 5.25c. St. Louis has been quoted at 5.17½c. Not much light is thrown on export sales, but that these have been heavy is undoubted. Shipments so far this month have been large, and would have been greater but for the difficulty of obtaining ocean freight room. Fear is entertained that the high prices which now prevail may lead to over-production, hence a surplus, all of which will tend to bear the market at a later date, perhaps excessively. Exports from November 1 to 26 totaled 5308 tons.

TIN

The stock of spot tin is so small that it ordinarily would create a scare, a rush to buy, and high prices, but the absence of demand is such that quotations have steadily declined. The quotation on the 24th was 39.25c. The situation is explained, at least in part, by the fact that consumers realize that they have been deceived a good many times of late. One rumor after another has been set afloat, not one of which proved to be true. It was falsely stated that the Suez Canal had been closed, that Great Britain was to place an export duty on tin, that the Straits Settlements were short of coal, that tin-bearing ships had been sunk, etc. Consequently, consumers have been holding aloof from the market and business has been almost nil. The arrivals this month total only 2000 tons. There was afloat on November 26, 4298 tons.

ANTIMONY

Spot antimony, Chinese and Japanese grades, is extremely scarce and 40c., duty paid, has been done. Needle antimony is said to be non-obtainable. Business has been confined to small lots of available grades.

ALUMINUM

The market holds steady at 58 to 60c. for No. 1 virgin aluminum, 99% pure.

COMPANY REPORTS

BATOPILAS MINING CO.

This well-known company, operating in the state of Chihuahua, Mexico, has issued a report for the years ended December 31, 1913 and 1914, and for the first eight months in 1915, during which periods operations have been considerably interfered with by the revolution. The American employees, who had returned to Batopilas in September 1914, left again in that month of 1915. The property is now in charge of trusted Mexicans. The report of the consulting engineer, Walter M. Brodie, contains the following:

The output in 1913 totaled 374,174 oz. silver, from 609 tons assaying 411 oz. per ton, and 20,278 tons of low-grade ore concentrated. About 75% of this came from the San Miguel property, where development was satisfactory, as it was in the Porfirio Diaz tunnel claims. Work at the Escritorio, Camuchin, and other mines was not very encouraging. The year 1914 was a bad one, as the revolution was at its height, but the company has been treated with great consideration by the people. J. R. Harbottle, the present manager, arrived in September of 1914. The bullion output by the company was 188,087 oz., from a total of 6635 tons of mixed ore. Development from September to December totaled 1206 ft. To August 31, 1915, the yield this year was 158,862 oz. Work has been resumed at the mines, stamp-mills, and cyanide-plants.

The profit in 1913 was $60,068, and in 1914, $10,556, a total of $70,624. Previous surpluses left a balance of $3,365,771 at the end of 1914. On October 15, 1915, the company had $87,247 cash in New York banks, and ₱47,500 Mexican currency and coin.

AMALGAMATED ZINC (DE BAVAY'S) LTD.

The report of this company, which treats Broken Hill tailings by flotation, covers the six months ended June 30, 1915.

During the period 156,196 tons of material was treated for a yield of 43,468 tons of concentrate, assaying 49.3% zinc, 5.5% lead, and 7.8 oz. silver; also 420 tons of concentrate, assaying 58.5% lead, 57.9 oz. silver, and 11.7% zinc. The mill was in operation for only 21 weeks, and the average production in respect of actual running time was 2070 tons of zinc concentrate per week.

No sales were made during the last two half-years. Contracts have been made covering the sale of 70,000 tons of concentrates at higher rates, consequently the profits on the production of the past twelve months will be eventually increased by approximately £155,000. The final figures will be available only on completion of delivery at the respective ports of discharge. So far, 33,000 tons has been shipped. Ninety per cent of the sale price is paid at port of destination, the balance later. Including revenue derived from dividends on shares in other companies, interest, rents, and exchange, and after deducting administration, income-tax, and all other Melbourne and London charges, the net profit (taking spelter at 4.5 cents per lb.) for the half-year was £21,999.

The surplus of assets at June 30, 1915, was £164,289. In the assets no account has been taken of tailings already paid for, but not yet treated (£101,483), nor of the 119,250 shares in Minerals Separation and De Bavay's Processes Australia Propy. Ltd. The accumulations of zinc and lead concentrates at the end of the term were 76,017 and 1479 tons respectively, the result of the War upsetting markets.

Metallurgical results were improved. The quantity of material treated by this company's process since it was installed is 2,562,000 tons, and the concentrate produced 730,000 tons, averaging 49% zinc. While the general manager, H. W. Gepp is in America, David Meredith is in charge.

Commercial Paragraphs

The Alaska Juneau Mining Co., Crocker building, San Francisco, through its managing director, J. H. McKenzie, and its consulting engineers, Messrs. Bradley, Bruff & Labarthe, have placed the following contracts for equipment for their new mill:

Westinghouse Electric & Mfg. Co., two 18-ton articulated electric locomotives, 30-inch guage of track.

B. F. Sturtevant Co., two high pressure fuel-economizers.

General Electric Co., one 9-stage Curtis turbo-generating set, 6000 kw., with direct-connected exciter.

G. C. Buchanan Co., one 36-in. by 48-in. Blake type all-steel jaw-crusher.

Power & Mining Machinery Co., two 4-compartment revolving car-tipples.

Babcock & Wilcox Co., through Chas. C. Moore & Co. of San Francisco, four class M, No. 30, Sterling water-tube boilers, with 826 sq. ft. of heating surface, each end equipped with Babcock & Wilcox steel super-heaters, working pressure 250 pounds.

Bonnot Co., twelve 8-ft. by 6-ft. ball-mills.

Petroleum Iron Works, through the Dorward Engineering Co. of San Francisco, one 55,000-bbl. capacity, steel fuel storage-tank.

Allis-Chalmers Mfg. Co., four No. 9 Gates type K gyratory crushers.

Kansas City Structural Steel Co., contract for the furnishing and erection of steel for buildings, aggregating 2500 tons.

Deister Machine Co., complete equipment of concentrating tables (150) and classifiers.

The value of all contracts placed as above is $458,864, f.o.b. factory, except where specified otherwise.

The Roessler & Hasslacher Chemical Co. of New York announces that its exhibit of cyanide at the Panama-Pacific Exposition, San Francisco, was awarded the gold medal.

In constructing the Arrowrock dam in Idaho, over 100,000 ft. of Leschen Hercules, plow and cast-steel wire rope, of ¾ to 2¼-in. diameter was used. One of the main cableway lines was a 2¼-in. locked wire rope.

The Allis-Chalmers Manufacturing Co., Milwaukee, Wisconsin, sends us Bulletins 1097, 1435-A, 1636, and 1801-A, dealing with power-transformers, vertical mill-elevators, hydraulic machinery, and the Isbell vanner. The descriptive matter and illustrations are of considerable interest.

The Morse Bros. Machinery & Supply Co. has purchased the entire plant of the Kuenzel process smelter at Buena Vista, Colorado, and will dismantle and ship it to Denver. This plant was never completed, and only parts of it were in operation. It is a complete power-plant of high-pressure boilers, engines, blowers, compressors, crushing-plant, machine-shop, fire and boiler feed-pumps, shafting, elevators, etc.

In English, Spanish, and Portugese, the Pelton Water Wheel Co. of San Francisco has published brief notes on the use of its wheel. This is intended to direct the attention of machinery users to the possibility of using Pelton drive for every class of apparatus, and also to more particularly instruct people living in remote districts where electrical energy is not available to the possibility of using a small stream for the supply of light, heat, and power through the medium of the Pelton system.

The company announces that Benjamin B. Lawrence, a member of the class of '78, has purchased the Pelton-Doble water-wheel and the Pelton-Francis turbine which were exhibited by the firm at the Panama-Pacific Exposition, and presented these to the Columbia School of Mines.

EDITORIAL

T. A. RICKARD, Editor

IF you want to be featured as an engineer of international fame, go to a boom camp and say kind things to the local reporter. If you want to find what a poor thing is fame, watch the incorrect spelling of your name in the local paper next day.

WE note that a committee of ten geologists, selected by the National Academy of Sciences, at the request of President Wilson, sails today from New York to the Panama Canal, in order to investigate and report upon the earth movements that have blocked the big waterway. The committee consists of Messrs. C. R. Van Hise, chairman, H. L. Abbot, John C. Branner, Whitman Cross, John F. Hayford, H. F. Reid, Charles D. Walcott, R. C. Carpenter, A. P. Davis, and John R. Freeman. The personnel of the committee is admirable, but why so many?

ON December 16 a convention of mining men is to meet at Washington for the purpose of urging upon Congress the necessity for revising the mining laws of the United States. This meeting is being held under the auspices of the Mining and Metallurgical Society of America, with the hearty co-operation of the American Institute of Mining Engineers and the American Mining Congress. The several sessions will be open to all persons interested in the industry of mining, but the right of voting will be limited to accredited delegates. We would suggest that our readers send telegrams expressing sympathy with the movement to the secretary, Mr. F. F. Sharpless, care of the Bureau of Mines, Washington. We shall do so.

THE latest re-arrangement of Guggenheim interests covers a wide area. It is proposed that the Kennecott Copper Company shall absorb the shares of the Braden Copper Company, the Guggenheim Exploration holdings of Utah Copper, the Alaska Steamship Company, and the Copper River railroad. This agglomeration of diverse properties may excite the cupidity of the public because the Bonanza mine of the Kennecott Copper Company is making big profits, available for dividends, on the realization of limited reserves of extremely rich ore, aided by the high price of copper. One apparent result is the disposal to the public of the Copper River railroad, which the Government did not buy, preferring to build the alternate line from Seward. This marketing of the railroad, which otherwise would be a loss, represents the obvious gain, to the Guggenheims, of this complex financial arrangement. Moreover, the delay in payment of dividends by the Braden, entailing probable further financing, will be covered by the immediate distribution made possible on account of the profitable operations at the Bonanza copper mine. Speaking generally, it may be assumed that such consolidations are made more to cover some deficiency than to improve operating efficiency.

IN rock-drilling and shaft-sinking practice the Lake Superior region takes the lead. Both the copper and the iron mines are excellent exemplars of progressive technique. Elsewhere in this issue we publish a description of fast driving in a mine of the Cleveland-Cliffs Iron Company. In this particular case, speed was essential. Therefore the ordinary tram-cars for hand-tramming were replaced by the large motor-haulage cars used for taking ore from chutes. Shoveling over the 5½-ft. side of these cars was severe work. Hence the company built in its shops the portable underground loader described. The total cost of this loader, including the 5-hp. motor, was $500. Such a loader can be built in any well-equipped mine-shop, and would undoubtedly be of service where speed of driving is desired. Efficiency-engineers will note that six shovelers were employed per shift instead of three, so that one gang could 'spell' the other; that is, the theory of rest-intervals, as promulgated in Taylor's system of scientific management, was used. Where speed is important and where the work is particularly tiring, there is no doubt that a double gang of workmen to relieve each other is worth while. The use of 80% dynamite, in this case for rock where the drift paralleled the slips, corresponds with the tendency of modern practice to use higher explosives. The method of blasting in two sections is a noteworthy feature; the miners on each shift completed the cut, making an average progress of over 12 feet per day of two shifts. The cost of $10 per foot is significant; of this $6.18 was for labor both underground and in the shops, and $3.82 was for supplies, the items including $2.33 for explosives, 24 cents for air, 40 cents for machine-repairs, and 3 cents per foot for carbide.

THE notes from the *Mining Magazine* concerning underground practice on the Rand, printed elsewhere in this issue, as to drilling short or long holes and the difference of gauge on successive lengths of steel, are most timely. Much the same problems of rock-drilling practice are engaging the attention of engineers and superintendents in this country. However, in several respects, results are being obtained in America almost exactly opposite from the trend of the conclusions stated to have been reached in South Africa. With high-grade intelligent miners as opposed to Kaffirs, American managements are favoring water-hammer

drills and hollow-steel, particularly in large mines where the rock is of medium hardness. Also, strangely enough, we are tending to drill longer holes for stoping, employing a decreased difference of gauge on successive drill-bits, even as low as $\frac{1}{16}$ inch. This practice of stoping on a larger scale, breaking a greater quantity of ore at one blast, has been aided by the use of special drill-bits (such as the Carr and H bits), making long holes possible because of their superior wearing qualities. Another factor now recognized is that it is more efficient to break down a large mass of ore in a stope by one big blast, even if the broken material should require block-holing, than to break ore in a stope by the old-fashioned small-scale methods necessary in driving. Again, American experience with hollow-steel appears more fortunate than in South Africa. Indeed, operators here have found it possible to decrease the difference in gauge of successive bits when using hollow-steel with mounted hammer-drills, in part because the hammer principle obviates the necessity for the reciprocating movement of the steel in the hole with a tendency to hit or rub against the sides. Another difference to be considered in comparing Rand with American practice is the extreme hardness of much of the rock in the South African mines; thus on the East Rand it is considered good practice if a small stope-drill can drill six or seven 6-ft. holes in one shift. This would be considered a poor performance in most American mines, although here again the difference between Kaffir labor and high-priced white miners is clearly evident. The entire subject of rock-drilling in all its details is arousing keen interest at this time, giving promise of useful economic results.

TUOLUMNE county, California, is attracting attention, as is shown by recent transfers of property. The old Rawhide mine, near Jamestown, formerly owned by Capt. W. A. Nevills, is being unwatered and re-opened by the Pittsburg Silver Peak Company. The mine was examined and re-opened on the recommendation of Mr. Duncan MacVichie, and will be operated with Mr. John Mocine as manager. A new head-frame has been erected, an electric hoist installed, and a new electric sinking-pump is to follow in a few days. The shaft is 1800 feet deep, on the incline, and has been idle for fifteen years. The mine was a famous producer, having yielded over $6,000,000. The Republican and Mammoth mines, near Jacksonville, have been taken over on a bond and lease by Mr. James T. Currie, of London, with Mr. F. W. Paige of Hodson as manager. These mines contain a large tonnage of low-grade ore and will be operated on a proportionate scale. Some high-grade ore has been produced in the Republican mine, which should afford a fine prospect. The Dutch, Sweeney, and App mines are being developed by Mr. W. J. Loring, of London, representing Boston capital. A new compressor is being installed at the Dutch mine, and the 40-stamp mill is being remodeled. Levels are being run from the Dutch to the App mine, the former being 1800 feet deep while the latter is only 1300 feet, so that exploratory work can be hastened. Other business is under negotiation by representatives of capital. All of which is highly gratifying to the people on the Mother Lode, of which Tuolumne county covers an important part. This famous mining region extends from the Cosumnes river to the Merced, a distance of 90 miles, across the foot-hill counties of Amador, Calaveras, Tuolumne, and Mariposa.

The Passing of the Exposition

Last Saturday, on the shore of the Golden Gate, one of man's greatest creative efforts came to an end. The gates of the Panama-Pacific International Exposition were closed and the work of demolition begun. A sum of $50,000,000 had been spent on the buildings and exhibits, the turn-stiles had counted 18,800,000 entrants, and the great show had been in evidence from February 20 to December 4. The time, the money, and the multitude were of impressive size. What was accomplished?

As a foregathering of the nations, the Exposition failed because the chief countries of Europe happened to be at war. Some of them were not represented by exhibits or were represented on a scale entirely disproportioned to the part they have played in the progress of the race. The pavilions enclosing foreign exhibits and the officials in charge of them served to give a slight flavor of internationalism, sufficient to emphasize the magnificent display made by the home country as a whole and also by the individual States. If the enjoyment of this wonderful display of the peaceful arts was marred by the reverberations of the organized calamity in Europe, the dominant thought among the visitors to the Exposition was not that they were fiddling while Rome was burning, but that the scene afforded a grateful contrast to the horrors of Armageddon. The War reduced foreign attendance, except from South America, to insignificant proportions, but it served to divert American tourist travel to California and caused many thousands to visit the Pacific Coast for the first time. Yet the bulk of the attendance came from the West, more particularly from California and the contiguous States. The Exposition was a pleasure ground, a gallery of art, a museum of industry, a marvel, and an inspiration to millions that had never had a chance to see such things before, and never will again. The pulse of the wearied globe-trotter might not be accelerated by the sights and sounds that had sprung into radiant being in the fairy-land created on the shore of the Bay of San Francisco, but to the farmer from the interior valleys, to the miner from the mountains, to the clerk from the village store, to the school-teacher from among the pinewoods, to such as these, the real people, the experience was one never to be forgotten. In a brief pause from familiar tasks they came wondering to the City of the Sunset, they wandered amid its courts and palaces, absorbed its tranquil beauty, read history in its inscriptions, glimpsed the allegory of its statuary, revelled in the frozen music of its architecture, gloried in the human achievement, rejoiced in the American accomplishment, and then journeyed home to treasure in their souls a memory that

will not die. Dreams are real while they last. This is

"A dream that shall not altogether die,
The vision of that day
When human strength shall serve the common good."

Co-operation, the momentum of joint effort, was the dominant note of the successive congresses that were convened during the period of the Exposition. The solidarity of feeling engendered by such meetings and interchanges of ideas may have gained by a side-long glance across the Atlantic, where the forces of disintegration seemed to be let loose. The use of the Exposition as a point of convergence for scores of professional, scientific, and benevolent organizations contributed to a rich increase of mutual acquaintance and goodwill. More particularly it afforded the people of the Pacific Coast and the countries bordering the Pacific Ocean an opportunity to compare notes. The islanders of the South Seas shook hands with the mountaineers of the Sierra Nevada; the Orient met the Spanish main on the hearthstone of America. From such commingling of the peoples will come social gain and industrial enlightenment. Among the particular events marking human progress was the beginning of telephonic communication across the continent and the opportunity afforded to visitors at the Exposition of speaking with their friends upon the Atlantic coast.

Was it worth while to spend $50,000,000? The question hardly needs further answer. Not as an advertisement of products, for most of those who came cared more for the pictures, the music, and the fireworks than to inspect the exhibits of the manufacturer; not as a place of idle amusement, for the arrangements for dining were poor and the banalities of the Joy Zone are best forgotten; but as a stimulus to the appreciation of beauty in art, to the widening of imagination, to the awakening of interest in new phases of human life—in these respects the Exposition repaid its organizers and enriched its beneficiaries. It was a liberal education to the multitude. In most cases the curiosity of the visitor was assuaged by the ready information of those in charge of the exhibits. The pictures told their own story, except those of the futurists and other cryptic artists; but it may be inferred with confidence that the lavish display of statuary aroused the poetic sensibilities that lie dormant even in the most practical mind and opened a new horizon to those of narrow groove.

And what did it prove? It proved that the men of San Francisco know no such word as fail. After the earthquake-fire they began to rebuild their city while the rest of the world was still wondering whether they could recover from the disaster. When they made plans for a celebration to mark the completion of the Panama Canal, the signs were propitious. But the Great War threw its dark shadow athwart their purpose. The Canal itself was blocked by landslips, so as to render traffic intermittent. Even the weather at first was unfavorable. Nevertheless those in control of the Exposition threw themselves into their work with keen intelligence and inexpugnable courage. They won. Seven months of superb weather aided them. The Exposition proves the unconquerable spirit of the Argonaut breed and the unexcelled beauty of the Californian climate.

"So fades that city, one with all that finds
The nameless road that Beauty takes at last—
One with her dust upon the twilight winds,
And all her music mingling with the Past."

Preparedness

Among the efforts to understand the vital question of preparedness for war, defensive or offensive, we may mention the investigation and report of the Union League Club, of New York. The fact that this work was done largely on the initiative of Mr. Christopher R. Corning, a distinguished mining engineer, simply serves to accentuate the fact that the defence of the country is a question in which the engineering profession is keenly interested, not only as thoughtful citizens, but as men that have undergone a training particularly serviceable for the purpose in mind. Copies of the report can be obtained from Mr. Corning at 36 Wall Street, so we need not quote from its many surprising statements, all proving unmistakably that the situation in this country is even worse than it was in England before the War. At least, England had a great navy, ready for action, while the United States is relatively worse prepared to protect itself from naval attack than it was a decade ago. A strong navy is a factor for peace, being mainly a weapon of defence and of protection to commerce. We hold that the United States should prevent not only danger to its life but threats to its peaceful industry, by establishing adequate naval protection from either invasion or piracy.

There is another kind of 'preparedness' for which we can plead with greater confidence. There are wars of tariffs as well as of armies. This country can, and will, keep out of the War, but it cannot escape the difficulties of trade created by active belligerency. When hostilities cease, there will be a scramble for business under new conditions, marking a divergence of many of the familiar currents of commerce. To young men we would say: learn Spanish. Great opportunities for American initiative will be offered in the countries of Central and South America. It may be that new openings, more especially work for mining engineers, will be available in Siberia after the War. Here also the knowledge of the language of the country is an essential equipment. For chemical engineers and for metallurgists, the War will furnish new opportunities. The necessities of the times, when the ordinary exchange of commodities is blocked, have caused inventive genius in Europe to find many subtitutes for materials and things heretofore purchased in America. Similarly a cessation of supplies of special chemicals or other manufactured products has caused our own people to invent substitutes. The general result is an upsetting of conditions and the necessity for envisaging a new order of things.

And there is yet another 'preparedness': disciplined

patriotism, a conscious social control as against a policy of drift. The War, despite its horrors, has shown how the soul of a people can be awakened to identity of interest and community of effort. If only a fraction of the wealth spent in munitions and a tithe of the unselfishness shown in the trenches could be perpetuated for service in the cause of social betterment, the world would have something to show for the bloodshed and suffering incidental to organized murder on a colossal scale. The subordination of individual desire to national purpose is a remarkable feature of the War, especially when viewed at a distance by a people of energetic individualists such as we are. The lesson conveyed by the spectacle should not be lost. The industrial conflict between capital and labor shames our material civilization as much as the howitzer and the submarine. It is a blight on democracy. Let preparedness for war go hand in hand with preparedness for peace. Preparation to die nobly is hardly less desirable than the preparation to live usefully.

Smelter Fume

One man's food is another man's poison. To the miner the smell of smelter smoke is a reminder of the profitable reduction of ore; to the farmer it is an irritant to throat and temper, and an agent of possible destructiveness to crops or cattle. During the last decade we have heard much of the clash of interest between smelters and farmers, with claims and counter-claims that indicated a gross misapprehension of facts on both sides. It is a relief therefore to turn to the report of the Selby Smelter Commission, recently published, and read the findings of an impartial tribunal, selected by the joint consent of the two parties in the case, namely, the Selby Smelting & Lead Co. on the one side and the people of the State of California, or, more particularly, the citizens of the county of Solano, on the other side. Protracted litigation, culminating in a decree of injunction, dated March 14, 1905, had brought matters to a crisis and threatened to terminate the useful activities of the chief smelter in California, when a conference between the attorneys representing both sides led to the submission of the question of fact, as to the violation of the injunction, to a committee of unprejudiced technical men. By a stipulation signed March 16, 1913, the complaint of the supervisors of Solano county was referred to a commission headed by the late J. A. Holmes, then Director of the U. S. Bureau of Mines, assisted by Messrs. W. F. Snow and Ralph A. Gould. Subsequently Dr. Snow retired in favor of Mr Edward C. Franklin, professor of organic chemistry in Stanford University. Mr. Gould is a chemical engineer resident in San Francisco. By leave of the Secretary of the Interior, the staff of the Bureau of Mines was placed at the service of the Commission. Among several contributions to the inquiry, we may mention the experiments of Mr. A. E. Wells on the effect of fume on vegetation and the investigation conducted by Mr. C. B. Dutton into the personal injuries alleged to be due to smelter smoke. The report contains much interesting information and establishes an excellent precedent for the settlement of similar disputes arising from the interference between neighboring industrial operations.

The conclusion, briefly summarized, is that visible smoke did injure horses prior to April 1914, when the new bag-house was built to filter the gases from the sintering furnaces. Lead and arsenic from this smoke were deposited on soil within the smoke zone, but in quantity so small as not to poison the soil or otherwise injure crops. With respect to the invisible fume—sulphur dioxide—it is found that the smelter did not maintain a nuisance, either by making bad smells or by economic damage to trees, shrubs, or crops. Finally, it is agreed that the mechanical devices now in use at the smelter are adequate to prevent such injury as may have been done in the past, but that to ensure the prevention of any sort of nuisance in the future the smelter management should observe sundry minor restrictions, specified by the Commission. Thus it is found that the smelting company was violating the terms of the injunction at the time when the Commission was organized, and was maintaining a nuisance, more particularly with respect to the injury to horses, but that by the addition of proper apparatus for the elimination of the visible element in the smoke, the smelting company has, since April 1, 1914, complied with the terms of the injunction "both in letter and spirit."

The report affords interesting evidence of the psychology of the case, showing how the residents of Benicia, across the strait on which the smelter stands, had become so prejudiced as to smell smoke when the plant was not in operation or when the sulphur dioxide was diluted to an extent quite beyond the possibility of detection by the most sensitive nose or throat. On the other hand, the Smelting company paid claims for horses reported to have been killed by the fume without investigating the cases, and thereby adopted a policy of "buying off" trouble. Not only did this encourage blackmail, but it became a cause of ill-feeling toward the rich corporation owning the smelter. Undoubtedly the average man resents bitterly the employment of money to suppress complaints, whether reasonable or not, realizing that the commercial method of abating trouble leads to all sorts of iniquities. As the Commission suggests, this misuse of money in attempts to silence protest from the farming population is responsible for much of the unreasonable dislike shown toward smelters by the neighboring communities. In the report it is stated: "the principle that right is on the side of the man with the biggest gun is fast becoming an obsolete idea in modern business and is being replaced by equity and open and above-board dealings." These last words describe the present policy of the Selby Smelting Company, which, by its willingness to arbitrate the matter, has shown good sense as well as public spirit. The lesson will not be lost on either of the two disputants, while to the Bureau of Mines the joint communities of mining and farming are under renewed obligation for a public service well done.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

An Early Ball-Mill

The Editor:

Sir—As a further proof of the correctness of the saying that there is nothing new under the sun, I submit for your consideration a photograph taken by me on the Mariposa Estate, belonging to the Mariposa Commercial & Mining Co., in Mariposa county, California, of a so-called Lundgren pulverizer, which is described by J. Ross Browne in his report on the Mineral Resources of the States and Territories West of the Rocky Mountains, made to the Secretary of the Treasury, March 5, 1868, page 30:

"The Bear Valley mill has 12 stamps. At this mill the Lundgren pulverizer and the Ryerson amalgamator are now being used. The Lundgren pulverizer is a barrel five feet in diameter and three feet in length made of boiler-iron three-eighths of an inch thick, heavily riveted. Inside, the barrel is shod with iron an inch thick. A door a foot wide and two feet long is placed lengthwise on the side of the barrel. There are two of these barrels at the Bear Valley mill and the cost of the two with their gearing was $2300, but if many were demanded they could no doubt be made for $1000 each. The barrels revolve horizontally, making 24 revolutions per minute and requiring a six horse-power engine for two of them. A charge is 800 pounds of quartz and 2400 pounds of ounce musket-balls made of chilled iron. The quartz previous to going into the barrel is crushed to about the size of grains of wheat and after being in the barrel one hour comes out an impalpable powder as fine as the finest flour. The powder is so fine that if it were pounded dry in the open air much of it would float away. The thoroughness of the pulverization is claimed to be the great advantage of the machine."

A RELIC FROM EARLY DAYS.

The present ball-mill, for which so much is claimed, is only an improvement of the Lundgren. This is another proof of the fact that many of the appliances for mining in the early days, while crude, were steps in the direction which we are traveling at this late date.

W. C. Ralston.

San Francisco, November 23.

Flotation on Dump Ore

The Editor:

Sir—On the eve of my departure from Australia I received a copy of your issue of July 31, in which considerable prominence was given to the subject of flota-

tion; and it has occurred to me that the following may be of interest to some of your readers.

Early last year I was commissioned to re-organize the work of the Lloyd Copper Company at Burraga, New South Wales, and, upon my arrival there, found that the concentration mill had been equipped recently with tube-mills and a flotation unit. I need not go further into the description of the plant than to state that when I assumed command the output of the mine and of the smelters was limited by the capacity of the mill, which was not working as well as it should have been doing. Attention was, of course, first given to the mill, which so well responded to the efforts made that before long it outstripped the supply from the mine, which was suffering sadly the consequences of lack of development. In the meantime I had made laboratory tests with regard to the flotation of the tailing lying on the dumps and had also sent away samples for trial at the experimental works. The results obtained from all sources showed that the sulphide in the tailing had become so oxidized that it had become totally unsuited for the ordinary process of flotation. However, before finally dropping the matter, I decided to give the tailing a bulk test and fed it to the mill during the ordinary course of crude-ore concentration. By this procedure I obtained such satisfactory results that dump-tailing was put through the plant with the crude ore whenever a shortage of the latter was anticipated. In order to find out definitely what recovery was being made from the dump-tailing, apart from the mixture of tailing and crude ore, an eight-hour run on tailing by itself was taken in hand. For the first two hours of the run everything went satisfactorily; but afterward the froth began to thin, and, finally, at the end of four hours there was no flotation at all, the particles to which the flotation bubbles were attached rising only part way to the surface in a manner similar to that which I had observed in my initial experiments on the flotation of zinc-blende by the Potter process at Broken Hill in 1902. The addition of sulphuric acid and other chemicals to the eucalyptus oil, which formed the frothing medium, had no beneficial effect.

At the end of four hours crude ore was put into circulation in the mill again; and very shortly afterward frothing recommenced, with the result that the flotation of the mixture of crude ore and tailing proceeded satisfactorily. Similar results were obtained during all the subsequent trials.

As my records are stowed away in the hold of this steamer, I am not, at the present moment, able to give accurate figures as to the recoveries obtained.

In smelting the flotation concentrate great losses were at first encountered. A big proportion by weight was lost in the roasters and again when the calcined concentrate was charged into the reverberatory furnaces. Clouds of calcined flotation-concentrate could be seen issuing from the top of the chimney-stack whenever the feed-hoppers containing the calcine were opened and the charge dropped into the furnaces. All kinds of devices were tried to overcome these losses, but they proved unsuccessful. As a final resort the 'green' concentrate, after having been well drained, was fed through the side doors (the rabbling doors) of the reverberatories and this procedure was ultimately adopted with satisfactory results. As the reverberatories frequently got ahead of the output of the mine and mill, they were, from time to time, used as roasters by being fully charged with 'green' flotation-concentrate and run with open doors for several hours until calcination had been completed.

I may add that at the works of the Wallaroo & Moonta company it has been found convenient to add to the top of each charge in the blast-furnace a definite quantity of 'green' flotation-concentrate, which sinters as the charge sinks and reaches the solidified stage before entering the strong blast area.

Prospectors, Engineers, and Amateurs

The Editor:

Sir—The Press of October 2 is at hand with its most interesting as well as entertaining letter from Mr. Richardson and your timely editorial reference to his letter. Reading these and the original editorial, 'The Amateur Miner,' in your issue of July 31, I am led to reflections on a series of correspondence, editorials, and technical dissertations that while differing in their purport have led to the same conclusion: the lack of new mines.

Five or six years ago readers were presented with numerous articles on how to sample a mine, these appearing under various titles. Some of these were admirable, assuming that you had a mine to sample. Indirectly but unquestionably they have influenced the prospective investor, also the development expert, until a general impression was created that the imposed conditions must be met for a safe investment. The result has been that nothing could pass muster but such a property as could present definitely blocked-out orebodies of definite value with prescribed mining and milling costs, and upon which the engineer can put a value, such as a lumberman would put upon a tract of saw-timber or a lumberyard. This did not preclude transactions in mines, but it did not bring in new mines.

Time passes: the pendulum continues in its swing, and the discussion merges into the query on the causes of the decline in prospecting. That this phase of mining has attracted more than passing interest is testified by the extent of the discussion and the prominence of the participants. Manifestly something was wrong, and many were the causes assigned therefor. No doubt some, possibly all, of the causes mentioned exercised influence, but there has been a master-key to the situation. Situated as I have been, intimately in touch with the prospector and the owner of the small undeveloped mine on the one hand, while, on the other hand not infrequently in the field with the investigating engineer, I have been forced to the conclusion that the largest factor in

inducing the so-called decline of prospecting has been the inability of the owner to market his prospect or undeveloped mine, for the simple reason that the requirements could not be met. In presenting reports on such properties, I have had them referred back, for property-maps, assay-maps, smelter-returns, photographs, estimates of tonnage, value of tonnage, etc., though, in the original, I had specifically stated that it was impracticable to furnish such data. Most of these engineers have insisted that there should be enough ore assured to justify the price of the property, interest on payments to be made for an arbitrary period; they have demanded the cost of mining and extraction, cost of equipment, interest on equipment for an arbitrarily set period of life, and on top of all of this, that "we should have a reasonable profit from the operations." With your editorial I can ask, have I not protested against the attempt to appraise mines on an investment basis?

Who will 'bring in,' to use the oil-well phrase, the new mines? The prospector is not able, the widow of the old-time prospector who left some patented claims as his legacy to his family, has not the means. I know she has good claims, I have advised capitalists to accept her offer and develop them, but will they, in the frame of mind superinduced by the impressions gained as mentioned above, consider such offerings? Not yet. But still the pendulum continues in its inexorable swing, the light is beginning to dawn and we may yet hope to see the day when there will be those, who, perhaps not like the old time 'adventurers' you mention but others with a keen mining business sense, will take up and 'bring in' the mines to be.

I do not agree with the man who says there are no prospects or mines to take hold of, that they are getting scarce. Our state offers many of these to the man who will leave his slide-rule and tape safely locked in his desk, and get out into the field with a sound experience, common-sense, and again quoting from your editorial "also some sort of instinct, based partly on inherited qualities, partly on experience, partly on keen powers of observation." Such a man will be invaluable to the investor who undertakes filling the gap now existing between the prospector, and the 'Development,' 'Mining,' and 'Exploration' companies of the day. This investor has the right to demand from such an engineer his opinion, and to receive it. Mr. Richardson says that if he were an engineer he would turn down the Little Tinker cold, and asks if you or I would recommend the Homestake, then or now? Honestly, if the engineer would spend his own money on the property under consideration, has he any right to turn it down cold, to his client, to Mr. Amateur Miner?

Finding fault without suggesting a remedy gets us nowhere. I would suggest to the 'Amateur Miner' and the many of him with whom the country is filled, that his capital may be well and profitably employed in filling this gap. Let him seek out an engineer who is honest, who knows his country, who knows the prospectors, the undeveloped mines of his 'stamping-ground,' and with him look over the field and select a few promising properties for exploitation. Judgment will dictate the spending of a few hundred dollars on this one, more money with encouraging results, or on the contrary, its rejection; a few thousand on No. 2, something on No. 3, taking or rejecting. On those selected, as standing the test of this preliminary investigation, proceed with development, open up, block out, map, sample, photograph, put up a test-mill, if advisable, and then say to Mr. Development Company: "We have a MINE for sale, here is our engineer's report—or that of some 'favorably known' engineer—we will sell it for so much, you may send your examining engineer, if you are in the market for a mine." Thus will Pap Brenegan be reincarnated in the modern business-man looking *for* a mine, not *forninst* one.

LEVERETT S. ROPES.

Helena, Mont., October 11.

Everson

The Editor:

Sir—May I add a few words to the editorial note in your issue of November 20, referring to Carrie J. Everson?

The investigation respecting her was initiated by the Colorado Scientific Society, which appointed a committee, consisting of Philip Argall, H. C. Parmelee, and the writer, to find out all that could be learned respecting her, and to suggest some means of commemorating her discoveries in flotation. The committee is still engaged in its work, and naturally would have preferred to defer any public presentation of its findings until ready to render its report. Unfortunately an ingenious newspaper reporter got wind of the affair, interviewed one of the informants whom we had located, and made up a characteristic 'story' which has been widely disseminated.

It is true that Carrie Everson is dead: and probably much of the history of the inception of the flotation processes has died with her. The later Everson-Hebron patent seems to mark rather a regression than an advance on the first patent. After the death of her husband, who was a Chicago physician, Mrs. Everson worked as a nurse, in order to support her son and herself. The friends who knew her at that time, speak most highly of her character and intelligence.

So far as we have been able to ascertain, she was not a school-teacher; and the story of her having discovered the efficacy of oil-flotation while washing ore-sacks in her brother's assay office is apocryphal.

GEORGE E. COLLINS.

Denver, November 27.

GEORGE STERLING has a beautiful poem of farewell to the Exposition in the December issue of the *Sunset* magazine. This poem is of higher quality than the one read during the closing ceremonial. The lines quoted in our editorial on the subject are his. The verse on the front cover is by William Watson.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Fuse burns at about 90 seconds per yard or half a minute per foot. A variation up to 10% either way has to be expected.

Magnesium is used in the manufacture of copper castings to prevent blow-holes by decomposing the gases formed in melting the copper.

Smelting and production of charcoal wrought-iron has been continuous at the Laxo Bruks Aktiebolag, at Laxo, Sweden, since 1642. The fires have never been out in the works.

The most northern railroad in the world is to be strictly an electric one. It is in Lapland, near Porjus falls, where the power-plant costing $5,000,000 was built by the Government. It is expected to transport iron ore from the great Arctic iron mines.

In turkey copper utensils constitute a form of savings-bank among the poorer classes. What money they can spare is invested in copper utensils as an addition to their stock, and when in need of money they sell what can be spared of their copper according to their needs.

Condenser water from steam-engines must be cooled before re-use. Several systems are used for this, including ponds, towers, and sprays. All have their advantages, those for the last named being saving in power, flexibility, less make-up water required, longer life, and lower first-cost.

When gold-quartz veins occur in slate, the slate walls usually carry iron sulphide which is gold-bearing, but to a less extent than the sulphide in the quartz. This sulphide in the slate is less massive than that in the quartz, and generally more flaky, sometimes requiring sizing or classification before concentrating.

Roller-bearings have two principal designs, one for straight radial loads and one for combined radial and thrust loads. Worn bearings cannot be adjusted satisfactorily; the rolling members and the races never wear equally, so that tightening a worn bearing, in order to eliminate the play, will jam some members while others will be loose, eventually destroying the bearing.

Water, not low temperature, causes the deterioration of roads in winter, according to road specialists of the U. S. Department of Agriculture. Cold weather does not in itself injure roads, no matter whether they are earth, gravel, or macadam. In fact, an earth road will stand more traffic when it is solidly frozen than at any other time. Excess water, however, is always detrimental to a highway. When cold weather turns this water into ice, the damage that it does is greatly increased. If the road, when winter begins, is thoroughly dry, with the surface and drainage in good condition, the chances are extremely favorable that it will come out all right the following spring.

A mine-superintendent writes to say that the ore being hoisted is so muddy that the hand-picking by boys on the picking-table in the shaft-house is much complicated. The mud is a result of the water from the Leyner drills that washes down a chute onto the broken ore. Some new raises now being driven for ventilation will take care of the mud, obviating the difficulty.

The Shattuck mine in Arizona contains a variety of ores in commercial quantities, including many forms of copper, lead, and vanadium. One of the sights in the mine is a cave, dome-shaped and white, 270 ft. long, 180 ft. wide, and 170 ft. high. The roof is covered with heavy stalactites, and the floor is composed of large and small crystals, in appearance like a coral bed, out of which rise magnificent stalagmites to the height of 20 ft. or more.

Grouting is now a recognized method of stopping flows of water in shafts, adits, and drifts. A mixture of cement and water (perhaps a bag of cement to three 12-qt. pails of water), with sometimes a little sand, is forced by a grout-machine into holes drilled in the rock, the pressure being furnished by compressed air. Pressure of 100 to 200 lb. above the hydrostatic head is used in difficult shaft problems. The Nova Scotia Steel & Coal Co., in its iron mine at Bell Island, Newfoundland, where the mine workings are several miles out under the ocean, has a grout-car run on wheels that can force grout into rock at a pressure of 700 lb. per square inch. By use of this grout-car the workings, although under the Atlantic ocean, are kept fairly free from large flows of water.

Rock-drilling practice on the Rand is criticized by E. M. Weston as follows: "In general the stoping practice and efficiency are much below what is believed to be possible. It is not known whether for work in flat stopes of the future, the path of advance lies in perfecting hammer-drills or in changing piston-drill practice. [In the Lake Superior copper region the question has been definitely decided in favor of mounted hammer-drills.—Editor.] In one mine it has been stated that hammer-drills are not a success, because, among other things, the cost of sharpening and replacing hollow drill-steel is twice as much as with solid steel for piston-drills. If we increase nominal drilling speed too greatly we are sure to increase the cost of repairs, drill-steel, break-downs, and delays. It may be a mistake to endeavor to attain high efficiency by paying too much attention to one factor at the expense of others. In South Africa air-pipes supplying drills at working-faces are often too small."

The Electrical Theory of Flotation—II

By THOMAS M. BAINS, Jr.

The article in the MINING AND SCIENTIFIC PRESS of October 23, 1915, by Mr. O. C. Ralston, has brought out many points of interest. It seems to me, however, that the fundamental principles of flotation can best be studied with larger particles, thus avoiding the interesting, but also little understood 'colloid' chemistry. In gravity separation by uprising currents of water, Rittinger's formula $V=c\sqrt{D(S-L)}$ holds true for particles above a certain size, namely, about 0.2 mm. for quartz and 0.13 mm. in case of galena. Below these sizes, colloidal and other little-known phenomena become of importance and complicate the investigation. So it is with flotation.

In the laboratory, it is possible to use larger particles. The following experiments were conducted in the Case School of Applied Science on material sized through 20 and 30-mesh screens. The phenomena connected with preferential flotation furnish new evidence to strengthen the electrical theory.

The simplest experiment, demonstrating preferential flotation, may be performed as follows: Upon a 4-inch watch-glass, place a little galena, blende, and quartz, of 20 to 30-mesh size. Add dilute nitric acid and place the glass under a microscope. The acid attacks the galena, forming bubbles of H_2S gas that adhere to the galena. The particles of galena are electrified also, as can be seen by the actions of the particles. The blende and quartz are not attacked. If the ore had been finely pulverized and dilute nitric acid added, the bubbles of H_2S would have been sufficient to float the galena, leaving the blende and quartz at the bottom. However, with fine particles, some blende and quartz would have been entrapped, brought to the surface, and held there by surface tension. The bubbles are not sufficient to float the coarse galena, but by a vanning motion of the glass, the galena will collect, being brought and held together by the H_2S bubbles, forming a mat, which is lighter than quartz or blende and can, therefore, be panned off, leaving the blende and quartz. This experiment seems to show that the H_2S is charged oppositely to the galena.

If more concentrated nitric acid had been added to the ore, the blende would have been attacked and the process would have been reversed, the blende forming the mat while galena and quartz were left behind. If dilute sulphuric acid, one part of acid to four of water, had been used, then both the blende and galena would have been attacked and if the ore had been finely pulverized, no 'preferential' separation would have resulted, both galena and blende finding their way into the float concentrate. However, with coarse material, the blende is much more highly charged than the galena and if the watch-glass be tapped and the contents given a vanning motion, the blende will gather most of the H_2S bubbles and finally float, leaving galena and quartz behind. This shows that the electrification of minerals varies with different acids and also with different strengths of the same. This action of one mineral, 'robbing' the others of their bubbles, has not been utilized in practice, as yet, but there is no reason why 'preferential' separations could not be made on a large scale, utilizing this principle. Less air or gas would be necessary than in the present type of frothing-cells and a clean concentrate would be produced at once. A separation of blende, galena, pyrite, and quartz may be made as follows:

Add dilute sulphuric acid and pan off the blende; then add dilute nitric acid and pan off the galena; then add concentrated sulphuric or nitric acid, which attacks the pyrite so that it may be panned off.

Or the separation may be made with nitric acid alone, varying the strengths; with sulphuric acid, by use of the 'robbing' action described above or by use of hydrochloric and other reagents that attack one or another of the minerals more strongly than the others. If galena or blende and magnetite be treated with dilute sulphuric acid, the magnetite will not be acted upon by the acid, but some of the H_2S bubbles generated by the sulphide will attach themselves to the magnetite, provided the bubble is formed near the magnetite. This illustrates the fact that electrical conductors in a conducting liquid attract electrified bubbles. A slight jar, however, will displace these bubbles; or a piece of sulphide in close proximity will rob the magnetite of the bubble, magnetite being a poor conductor.

Referring to the article on page 668 of the MINING AND SCIENTIFIC PRESS of October 30, 1915, describing a patent for preferential flotation of blende, galena, and pyrite, the second paragraph reads: "The new process consists of treating ores in a medium (i.e. sulphuric acid and sodium sulphite) that wets the zinc sulphide and which does not wet the lead sulphide or pyrite." This phenomenon brings out nicely the part played in flotation by the "dielectric film." When thio-sulphates, sulphites, or bi-sulphites are acted upon by sulphuric acid, there is more to the phenomenon than formation of SO_2 gas. The following reactions take place when blende and galena are treated with sulphuric acid and sodium sulphide:

$$ZnS+PbS+2H_2SO_4=ZnSO_4+PbSO_4+2H_2S$$

$$*Na_2SO_3+H_2SO_4=Na_2SO_4+H_2O+SO_2$$

$$\dagger 2H_2S+SO_2=2H_2O+3S$$

This sulphur thus formed is in a very fine state and acts as a dielectric film about the galena, for which it has

*Newth's 'Inorganic Chemistry,' p. 417.

†*Ibid.*, p. 436.

a great attraction. Therefore, no frothing agent is needed in this case, as the dielectric film about the bubbles is formed by the sulphur similarly to the films of oil formed in the ordinary flotation processes. In the last paragraph of the above-mentioned article on 'Preferential Flotation,' the statement is made that "the procuring of the effect aimed at, is dependent upon the presence of a frothing agent, *only* when a reducing gas is *introduced* into the medium. It is not dependent on the presence of a frothing agent in the flotation medium, when a reducing gas is *generated* in the flotation medium by a reaction of a substance introduced into it." In other words, if sulphur or any other 'dielectric' is liberated in a very fine state, by a "reaction of a substance introduced," no frothing agent need be used.

This action may be nicely illustrated by taking 20 to 30-mesh galena and blende and treating them with dilute nitric acid on a watch-glass and observing the result under a microscope. The galena will gather all the H_2S bubbles, when vanned. Now if sulphuric acid is added and the watch-glass be tapped and the particles moved over one another, the H_2S bubbles on the galena will be robbed by the blende. Sulphur may be seen surrounding the bubbles, the reaction being as follows:

$$ZnS+PbS+2H_2SO_4=ZnSO_4+PbSO_4+2H_2S$$

$$(1)\ H_2S+H_2SO_4=SO_2+2H_2O+S$$

$$(2)\ 2H_2S+SO_2=2H_2O+3S$$

In (1), the sulphur is formed from the decomposition of H_2S; and would be charged oppositely to the sulphur formed by the decomposition of SO_2 gas. In (2), we have both negatively and positively charged sulphur particles.

The larger bubbles, with sulphur particles adhering to them, may burst on reaching the surface and their film of sulphur will spread over the water. If particles of mineral had been attracted to the bubble, then these particles would have remained attached to the sulphur film, even after disruption of the bubble, showing the electrification of the dielectric film. The same phenomenon occurs when the film is a liquid dielectric, like oil.

The laboratory tests with chemical reagents generating H_2S gas give the opposite results from the regular air-bubble flotation. The ordinary flotation method in practice is to add a little acid and frothing agent to the pulp. The sulphides are positively charged by friction, while the frothing agent and air are charged negatively. The oil surrounds the sulphides, but the film is so thin that the negatively-charged bubble is attracted by the positively-charged sulphide. If the film of oil is too thick, the attraction between the sulphide and bubble is too feeble, and flotation fails.

In the laboratory, H_2S is charged positively, but the sulphides are charged negatively by chemical action. So the bubble attaches itself to the electrified sulphide.

In preferential flotation of galena and blende, in practice, the ore is treated with H_2SO_4 and Na_2SO_3. Sulphur is liberated and the galena is coated with the particles of sulphur positively-charged, while the negatively-charged sulphur coats the gas bubbles. The negatively-charged air bubbles of the flotation machine attach themselves to the positively-charged sulphur coating the galena and repel the negatively-charged blende.

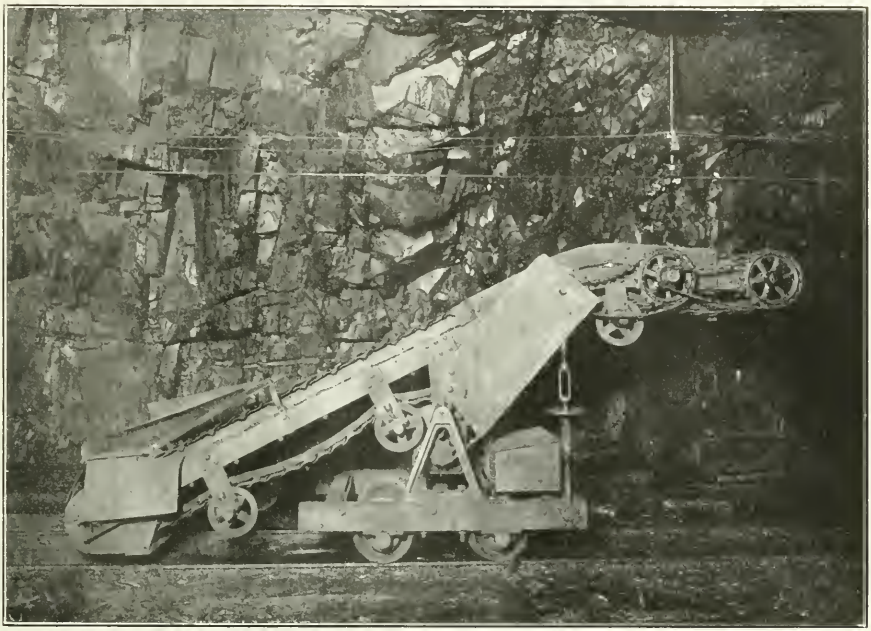
In the laboratory experiments, the H_2S bubbles are charged positively and are attracted to the negatively-charged blende and repelled by the positively-charged sulphur on the galena. In this case, the blende is floated. When H_2S is blown into the pulp in practice, no sulphur is formed—the H_2SO_4 solution being too weak for this reaction. Therefore, to make a persistent froth, a frothing agent must be added to the pulp.

In conclusion, it may be well to call attention to the fact that for laboratory experiments in preferential flotation, any one of the sulphides may be separated from the other sulphides, (*a*) by the use of some reagent that attacks this particular sulphide and not the others, (*b*) by the use of a reagent that attacks one sulphide more vigorously than the others; in this case, the vanning motion allows the sulphide more highly charged to gather up the bubbles from the sulphides less highly charged, and if sufficient bubbles are collected, the mass of bubbles and sulphide will float. If not sufficiently buoyed, the mass remains submerged, but it is lighter than the other sulphides or gangue minerals and can be panned off or separated by hydraulic classification.

The second point of interest is the formation of a frothing agent, within the pulp, when reactions take place that liberate dielectric substances in a very fine state, electrically charged.

The third point is that laboratory experiments may not work out in practice, due to failure to understand the nature of the electrical charges of the bubbles, dielectrics, and particles of ore. A little stronger reagent or a different way of frictionally electrifying the bubbles and pulp, or too thick a film of dielectric or frothing agent causes the attraction to cease or change. It is no wonder that great difficulty has been experienced in the practical application of flotation to ores, when such delicate electric forces have to be considered.

TUNGSTEN, it is asserted, can no longer be considered a rare metal, since as far back as 1913, the tungsten output of the world exceeded in weight that of the combined production of mercury, gold, bismuth, and cadmium. In 1913, the United States produced 1397 metric tons of tungsten ore (60% WO_3); as compared to 1732 tons produced in Burma; 1403 tons in Bolivia, Peru, and Argentina; 1380 tons in Portugal, and 752 tons in Australia (principally Queensland). In the United States, Boulder county, Colorado, is the largest producer, ferberite or iron tungstate being the principal ore; the Atolia district in the Mohave desert of California is the largest scheelite (tungstate of lime) producer in the world; hübnerite (tungstate of manganese) deposits are worked in Arizona, Idaho, and Nevada; some wolframite (tungstate of iron and manganese) discoveries have been made in South Dakota and New Mexico. The Conger mine, in Boulder county, Colorado, is said to be the greatest mine of its kind in the world, having produced nearly $1,500,000 of tungsten.



PORTABLE ROCK-LOADER MADE AT THE SHOPS OF THE CLEVELAND-CLIFFS IRON COMPANY.

Fast Driving in a Michigan Iron Mine

By J. E. HAYDEN

*The Morris-Lloyd mine of the Cleveland-Cliffs Iron Co., is situated at North Lake, four miles west of the City of Ishpeming. At a distance of 3000 ft. east of the Lloyd shaft, an orebody was discovered by diamond-drilling from surface. In the fall of 1914 it was decided to open up this orebody by driving from the Lloyd shaft on the 600-ft. level. A 9 by 10-ft. heading, without timber, was driven due east from a point 350 ft. south of the shaft in the slate foot-wall, which strikes almost due east and west, and dips at an angle of 85° south.

The drift was started on September 1, 1914, and completed on June 17, 1915, a distance of 2960 ft. having been driven in 240 working days. The record month was May, 1915, when 406 ft. of drift was done in 26 working days. During this month the best day's progress was 19 ft. 9 in. (due to a partly missed-cut on the previous shift); the poorest day's was 12 ft. 9 in., the average daily progress being 15 ft. 8 in. The average monthly progress throughout the 9½ months was 311 ft. 6 in., the average daily progress being 12 ft. 4 inches.

The rocks traversed were slate, graywacke, and quartzite. The work was done on two 8-hour shifts; 4 miners, and, for the greater part of the time, 6 shovelers constituted the crew. The shovelers alternated, one gang of 3 filled a car, while 3 rested. Two No. 18 Ingersoll-Leyner drills were used throughout the work, except for the first 100 ft., when two 3¼-in. piston machines were used. Electric-motor haulage was used in 2300 ft. of the drift, and hand-tramming in the first 600 ft. Permanent track on a 0.75% grade was laid and kept to the face. The trolley-wire was kept within 150 ft. of the face, the shovelers tramming the car this distance to the motor. At intervals of 300 ft. along the drift, sidings were cut to hold three motor-cars. Throughout the work, 80% nitro-glycerine dynamite was employed. The fact that the drift paralleled the slips made it necessary to use a strong explosive to insure breaking the cut, as the ground was extremely tight. This also eliminated large chunks and threw the broken rock a considerable distance from the face, enabling the miners to rig-up quickly for drilling the next cut.

As the ground varied considerably, it was necessary to vary the cut. Fig. 1 and 2 represent the two cuts used. Fig. 1 was the cut commonly adopted for driving in slate, and Fig. 2 when in quartzite and graywacke. In Fig. 1, holes 1 to 11 were drilled from the bar in one

*Abstract of paper presented at 1915 meeting of Lake Superior Mining Institute.

position, and fired in one blast. To complete the square all 14 holes were fired on the second blast. It was found that good results were obtained only when holes 5-6 and 9-10 intersected at their respective ends. This point was carefully watched, the shift-boss testing these holes before each blast. For the extremely hard ground, such as the quartzite, the cut was made as in Fig. 2, the top 15 holes being fired in the first blast, and all 19 holes to complete the second cut and square. The two relief-cut holes (see Fig. 2), were drilled to meet at a depth of 3 ft. For the moderately hard ground, such as the graywacke, two easing holes were drilled as in Fig. 2, instead of the 3-ft. relief cut.

Fig. 3 shows the cycle of operation to complete the square, *A* representing the portion removed in the first blast, *B* that portion removed in the second blast. Each shift blasted twice, completing the cut, leaving the drift squared. During the entire progress of the work, there

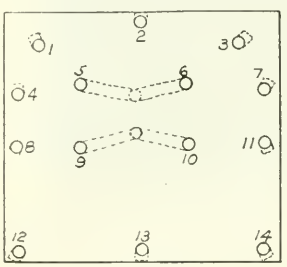


Fig. 1.

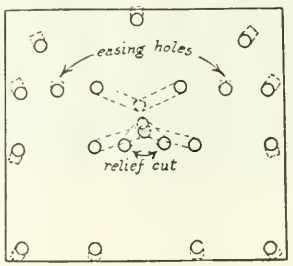

Fig. 2.

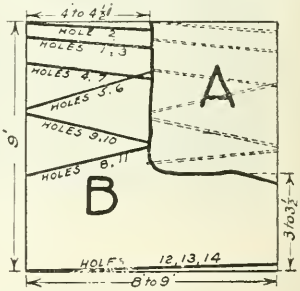

Fig. 3.

was but one slight injury, that being caused by a piece of rock hitting a miner's hand while barring down loose ground from the back.

Three-ton saddle-back motor-cars were used; These had a height of 5 ft. 6 in. above the rail in the clear, which necessitated much shoveling. This difficulty was overcome by the installation of a portable loader during the latter half of April. This loader consisted of an inclined steel-apron conveyor-belt with 2¼-in. angle-irons placed 15 in. centre to centre, mounted on a roller-bearing truck, operated by a 5-hp. series motor taking current from the underground-haulage wire. The loader was arranged so that the angle of the incline could be reduced, allowing it to pass under the trolley-wire. The men shoveled into a hopper at the lower end of the belt, the rock being conveyed up the incline and dumped into the motor-car. A small part of the rock could be picked down from the pile into the hopper. Three men shoveled, while one trimmed the car. The work was hastened after the loader went into commission, as it became possible to handle more rock. Within a week the output was increased 25%, and later on it often reached 30%. The whole cycle of operations was completed earlier on the 8-hour shift, giving more time for drilling, consequently deeper cuts were tried, with extra holes, to insure breaking.

At a distance of 1220 ft. from the shaft, a fan-station artificial ventilation was used in the 1220 ft. of drift up to the fan-station. As most of this work was done during cold weather when the shaft was strongly up-cast, the blowing of air in the breast was sufficient to clear the drift in 30 minutes.

The following is a detailed cost of the 2960 ft. of drift:

	Labor.	Supplies.	Total.	Cost per ft.
Miners	$ 8,430.27	$ 1,587.73	$10,018.00	$ 3.384
Shoveling	8,169.03	.....	8,169.03	2.760
Tramming	1,117.92	498.39	1,616.31	0.546
Explosives	.....	6,889.86	6,889.86	2.325
Air	.....	720.00	720.00	0.244
Shop-expense	460.00	230.00	690.00	0.233
Machine-repairs	135.50	1,196.27	1,331.77	0.451
Air and water hose	.....	75.00	75.00	0.025
Carbide	.....	95.00	95.00	0.032
Total cost	$18,312.72	$11,292.25	$29,604.97	$10.000
Per foot	6.18	3.82		

The value of mineral production of the United States in 1914, according to the U. S. Geological Survey, was $2,114,946,024, being exceeded only by that of two years —1913 and 1912. The metallic products in 1914 were valued at $691,000,343, and the non-metallic products at $1,423,395,681. The bound volumes (2), of 'Mineral Resources of the United States' for 1914 will soon be ready for distribution. They deal with metals and non-metals respectively.

Plant-Construction Costs in Korea

By A. E. DRUCKER

Construction costs are of great value for particular districts; they vary largely in different parts of the world, depending more or less on labor and transportation. It is customary to add from 10 to 20% of the estimated cost as a safety factor, depending upon the engineer's knowledge of the district in which the plant is to be erected.

Herewith I give an itemized account of the actual cost of a re-treatment plant in Korea. It was designed to retreat an old cyanide tailing-dump containing about one-half sand and the remaining half sulphides of iron, zinc, and lead. This mixed product was caught originally on Union vanners in a 40-stamp mill and cyanided for 16 days in leaching-vats. The method of treatment for this old oxidized dump was screening, washing, and concentrating on Wilfley tables. The clean sulphide product, containing 80 to 90% of the original gold-value, received a preliminary air-agitation with lime and water. It was then de-watered, tube-milled in cyanide solution, and received a final cyanide treatment in Callow decantation cones, Pachuca tanks, and a Dehne filter-press.

KUK SAN DONG MILL, KOREA.

The plant consisted of one stock-solution tank 15 by 10 ft. deep, one water-supply tank 15 by 15 by 10, weigh-bridge, storage-bins 10 by 20 by 10 and 20 by 20 by 10, one tube-mill 4 by 16 ft., one 3-in. sand-pump, one screening mill 5 by 3 ft., two double-cone classifiers, six Callow cones, four Pachuca tanks 8 ft. diam. by 30 ft. high, eight Wilfley tables, two sand-filter tanks, each 10 by 6 ft., four (6-comp.) zinc-boxes, two solution-sump tanks 15 by 10 ft., one monteju, one 24-frame Dehne press, two centrifugal solution pumps, one steam-compressor, one belt-driven compressor, two vacuum-pumps, one Pachuca lime agitation-tank with concentrate-collecting boxes and bucket-elevator.

Steam was used to operate the plant. There were also the necessary stone retaining-walls and concrete foundations. The building was a wooden structure covered with corrugated sheet-roofing. All cyanide tanks were of steel plate.

The cost of construction is summed up as follows:

DUMP RE-TREATMENT PLANT CONSTRUCTION

Salaries	$ 2,276.60
Board	219.99
Supplies	24,524.32
Pay-roll	3,399.86
Shops	5,543.87
Stable	90.00
Total	$36,054.64
Expenses in May (testing plants, etc.)	3,282.00
Grand total	$39,336.65

This plant had a maximum capacity of 60 tons per 24 hours on dump material averaging 50% of sulphides. The total cost of construction was $39,336, being at the rate of $655 per ton of capacity per 24 hours.

TARACOL STAMP-MILL (original). Eighty 1050-lb. stamps, four Blake crushers, thirty-two 6-ft. Frue vanners, 16 copper amalgamating-plates, and steam-power plant. Capacity of plant, 360 to 365 tons per 24 hours, with 25-mesh battery-screens and low discharge. Original cost of plant was approximately $128,000. Now operated by electric power.

TABOWIE STAMP-MILL (new addition. Forty 1050-lb. stamps, two Blake crushers, sixteen 6-ft. Frue vanners, eight copper plates, and steam power-plant. Capacity of plant, 170 to 175 tons per 24 hours, with 25-mesh screens and low discharge. Original cost of plant was approximately $66,000. Now operated by electric power.

CANDLESTICK STAMP-MILL. Ten 1050-lb. stamps, one Blake crusher, two copper plates, three cone-thickeners, four mechanical agitators 15 ft. diam. by 10 ft. deep, four sand filter-tanks 12 by 6 ft., six zinc-boxes, three sump solution-tanks, pumps, and steam-power plant. All cyanide tanks are of wood. Capacity of plant 25 tons. Original cost $27,000, approximately.

THE ADVANTAGES OF CANADA'S BANKS and banking systems, with branches in nearly every city, lie in the facility with which the money of the country can be shifted to the district where it is needed, for harvesting, logging, or mining, varying with the season. Money is raised in the Eastern cities where interest is low, and forwarded to new Western towns where it is most needed. It is stated that in the early days at Porcupine, when the railroad was 35 miles away, there promptly sprang up branches of the great Canadian banks in scrubby log-cabins, in which business was conducted as capably and satisfactorily as though the permanence of the camp was a foregone conclusion.

Precipitation With Zinc-Thread

By JAY A. CARPENTER*

The purpose of this article is to give data on precipitation with zinc-thread at a Tonopah mill and to show that this method, although second in efficiency to the use of zinc-dust, gives excellent results when operated under favorable conditions. There seems to be a tendency in articles published in the technical press to extoll the virtues of any new method, to the disadvantage of the old one. At the time of the growing popularity of the Pachuca agitator it would have been heresy to publish the fact that they filled gradually with solidified pulp, and it was not until their popularity was on the wane that this was asserted in print. Likewise, zinc thread or shaving, once so popular because it won in competition with electric precipitation, is now only mentioned for its disadvantages. Even such an excellent paper as that of G. H. Clevenger on precipitation methods (presented at the International Engineering Congress) contains the inference that zinc-thread is greatly outclassed by zinc-dust. It is true that zinc-thread precipitation has its bugbear, namely, the white precipitate, but it is also true that with precipitating-presses, a bad cask of zinc-dust, or some other reason safely locked in the iron press, may cause the metallurgist just as much worry. Occasionally muddy solutions give trouble in zinc-boxes, but they play havoc in zinc-presses. Zinc-boxes may be subject to petty theft, but the bulk of the precipitate is not in a frame waiting the hold-up man. It has been said that, "comparative costs of zinc-dust and zinc-shaving show considerable advantage in favor of zinc-dust," but special mention should also be made of the fact that by the time the mill is provided with the heavy metal presses necessary to clarify and precipitate the solution with zinc-dust, the investment is so greatly in excess of the simple zinc-boxes that the saving made with the dust must extend over a long period to balance the greater outlay of capital. When the metallurgist considers the large number of mills that never pay back the capital invested, this point should cause him to consider the less efficient but cheaper methods, to see if their efficiency cannot be improved sufficiently to warrant installation.

In designing the West End mill in 1911, from data on silver cyanide-plants, I decided that five tons of solution should be precipitated for each ton of ore treated, or 600 tons for the 120-ton mill-capacity, and that this 600 tons required 0.75 cu. ft. of zinc-shaving for each ton, or 450 cu. ft. in all. Six redwood boxes were built, each with six compartments 30 by 30 by 24 in. deep. Below the screen of each compartment was a double hopper, which discharged through an 1½-in. plug-cock into a gravity system of launders leading to the precipitate vacuum-tanks. At the end of the first three months' operation the consumption was 1.7 oz. troy of zinc for each troy ounce of refined gold and silver recovered. About four tons of solution had been precipitated per ton of ore. This solution was made up as a 6 lb. KCN solution, with 1 lb. protective alkali, expressed as NaOH. The cyanide titration is made for total cyanide without any additional alkali, and we titrate for the protective alkali without the addition of ferro-cyanide. This high zinc consumption was probably due to the fresh strong solution, but it resulted in a local hunt for comparative data, which were recorded as shown herewith:

	Montana. 1908.	Extension. 1911.	Desert. 1910-'11.	Belmont. 1910-'11.	West End. 1911.
Zinc used per oz. of bullion, lb.	0.108	0.065	0.084	0.09	0.11
Zinc per ton solution p'p'ted, cu. ft. Dust		1.57	0.81	0.75	0.87
Solution p'p'ted per ton of ore, tons	2.75	4.0	5.5	4.5	4.0
Bullion per ton of ore, oz.	8.5	17.0	21.0	20.0	15.5
Troy oz. zinc for troy oz. Au and Ag in bullion	1.67	0.945	1.22	1.31	1.7

Believing that the high consumption of zinc at the West End was partly due to buying zinc already cut (about a 1/600-in. shaving), a zinc-lathe was installed, and fresh zinc was cut as needed, about 1/300 in. thick. Results in 1912 were much better, there being a zinc consumption of 1.18 unit-weights of zinc for each unit-weight of refined bullion, but with only about 0.8 cu. ft. zinc per ton of pregnant solution, averaging 4 oz. in silver and 0.04 oz. gold; the precipitated solution still contained 0.10 oz. to 0.30 oz. silver. This precipitated solution, used as filter-cake barren-wash, resulted in high soluble losses.

In 1913, two 120-cu. ft. iron zinc-boxes, each having seven compartments 36 by 24, and 32 in. deep, were added; one to precipitate solution to a low value for filter-cake wash solution, the other to precipitate the wash-water circuit on the filter. The quantity of zinc-shaving in this second box, and the tonnage of wash-water precipitated by it, are not considered in the following table, but its zinc consumption and the bullion produced by it are included. This box precipitates about 2000 tons per month of wash-water, drawn through the filter-cake by a vacuum-pump and carrying about 0.4 oz. silver, giving a precipitated solution containing a trace to 0.02 oz. of silver. These boxes resulted in impoverishing the precipitated solutions used as filter-washes, and allowed the wooden boxes to be used for incomplete precipitation. An increase in ore tonnage nearly offset the increase in zinc-box capacity. However, for the year 1913 the consumption of zinc was 1.48 unit-weights of zinc for each unit-weight of refined bullion. This was due to an increase in alkalinity of the pregnant solution, and to a

*Mill superintendent, West End Con. Mining Co., Tonopah, Nevada.

policy of keeping the short zinc at a minimum quantity.

In 1914, with an increase in the reduction-plant to treat 200 tons per day, two more iron zinc-boxes were added to the complete precipitation circuit, resulting in an increase in area of zinc per ton precipitated. Less solution was precipitated per ton of ore, more 'shorts' were allowed to accumulate in the boxes, and a pregnant solution of higher value somewhat lower in cyanide and alkali was precipitated, the combination resulting in a decrease in zinc consumption for 1914 to 1.27 units for each unit of refined bullion.

The mill-solution that had been carried at over 6 lb. KCN in 1912, was dropped to 5.3 lb. in 1914 on the same grade of ore, and in January to April 1915 it had been lowered to 4.4 lb. on a better grade of ore. In May it was reduced to 3 lb. on the same grade of ore. The protective alkali that had been carried above 1.0 lb. protective NaOH up to 1915, was lowered to 0.7 lb. The result for the month was surprising, as the zinc consumption was only 0.66 unit zinc for each unit-weight of refined bullion, or expressed in ounces, 0.66 oz. troy zinc for each ounce gold and silver recovered in the bullion. Results during the following months were watched with great interest to see if May was exceptional, or if a method of saving zinc had really been proved. For six months now this low record has been maintained. In spite of a variation in the ore from $13.50 to $19.60 per ton, the zinc has varied likewise, resulting in a consistent consumption of zinc for the bullion recovered. The monthly mill-reports show the following consumption of zinc in pounds per ounce of refined bullion extracted: May, 0.044; June, 0.05; July, 0.045; August, 0.044; September, 0.044; and October, 0.045 lb. The average is 0.0453 lb., which is equal to 0.66 oz. troy zinc for each ounce refined bullion. A summary of the precipitation record described above is given in the following table:

PRECIPITATION RECORD AT WEST END MILL

	1911.	1912.	1913.	1914.	Jan.-Apr., inc., 1915.	May-Oct., inc., 1915.
Tons of ore per day	120	123*	140*	179*	155	158
Bullion recovered per ton, in oz. fine	15.5	15.4	17.9	15.3	19.1	23.6
Solution precipitated per ton of ore, tons	4.0	4.1	4.0	3.3	3.5	3.5
Bullion precipitated per ton of solution, in oz. fine	3.9	3.8	4.5	4.7	5.7	6.4†
Solution precipitated, incomplete, in tons	..	...	490	380	341	352
Solution precipitated, complete, in tons	480	500	70	210	202	202
Zinc per ton of solution p'p'ted, incomplete, in cu. ft.	..	...	0.85	1.10	1.23	1.19
Zinc per ton of solution p'p'ted, complete, in cu. ft.	0.90	0.84	1.70	1.70	1.70	1.70
Zinc per ton of solution p'p'ted, part and complete average, in cu. ft.	0.90	0.84	0.96	1.32	1.44	1.41
Total zinc, cu. ft.	420	420	540	780	780	780
Zinc used per ton of ore, lb.	1.70	1.25	1.80	1.34	1.46	1.01
Zinc per oz. of bullion, oz. troy	1.70	1.18	1.46	1.27	1.21	0.66

*Concentration throughout 1913, and about one-half of 1912 and 1914, removed other metal from the ore, in addition to that shown as bullion.

†The ratio of gold to silver is about the same as in the ore, namely 1:100, which, estimating gold at $20 per oz., and silver at 50c. per oz., gives a value of 70c. per oz., or for 6.8 oz. a value of $4.76.

In 1915, from January to April, inclusive, the tonnages of ore and pregnant solution were both considerably less than in 1914, resulting in a marked increase in cubic feet of zinc per ton of solution precipitated, yet with a decrease in the cyanide and alkali strength of the pregnant solution, made with the idea of saving cyanide, there was a distinct drop in zinc consumption to 1.21 units of zinc to each unit-weight of refined bullion. With the price of sheet-zinc soaring to an almost prohibitive point, it was decided to cut the cyanide and alkali strength of the pregnant solution as low as was consistent with good extraction, the drop in cyanide strength to be balanced by keeping the mill-solution fresher, and therefore more active.

The most important conclusions to be drawn from these results is that the high cyanide and alkali strength of the pregnant solution is responsible for the high zinc consumption in silver cyanide-plants. Another point of importance is that a greater volume of zinc-box capacity for a given tonnage of solution does not increase zinc consumption, but rather tends to decrease it by allowing ample space for the care of the short zinc.

Zinc consumption in 1915, as shown in the table, where a small quantity of rich solution is precipitated per ton of ore, is low compared with mills precipitating large volumes of solution of lower grade. In a recent description of a silver mill, 'Cyanide Practice of Churchill Milling Co., Wonder, Nevada,' A. I. M. E., San Francisco meeting, Sept. 1915, treating an ore of about the same gold and silver-content, but using a 4.6 lb. KCN and 1.6 protective CaO solution, and precipitating 6 tons of solution per ton of ore, which was over 2 tons per cu. ft. of zinc-shaving, the zinc consumption was given as 1 lb. for each 10.19 oz. bullion. This represents about 1.5 oz. troy zinc for each ounce of refined bullion, which is close to the results obtained in the Tonopah mills using high cyanide and alkali solutions, and precipitating on zinc-thread a large amount of solution per ton of ore. It would probably hold true also in continuous-decantation plants, where the tendency is to precipitate a maximum tonnage of solution.

Work on the zinc-boxes at the West End mill varies but little from standard practice. The boxes are cleaned twice per month; all precipitate passing a 20-mesh screen is melted, the remainder is returned to the first two compartments of all the boxes as short zinc, where it is mixed with a little of the zinc moved up from the third and fourth compartments. The last compartments are left empty, to be filled when the value of the precipitated solution increases before the next clean-up. Between clean-ups the short zinc is occasionally shaken by catching a hook in the screen below it. Channeling in all compartments is prevented as much as possible. If too much slime has reached the boxes, the zinc may be washed, moved up, and re-packed. The strips of zinc left from cutting the sheet-zinc on the lathe are divided into small pieces, and mixed with the short zinc, serving for a time the purpose of holding the shorts apart.

The rich solution passing through the short zinc in all of the first two compartments loses much of its metal content to them, thus protecting the long zinc, and at the

same time consuming much of the short zinc. In 1913, on account of limited zinc-box capacity, we tried the rather foolish plan of melting shorts, and later of tube-milling them in pregnant solution, but the net result was a useless consumption of zinc with as much shorts as ever, due to placing long zinc in the first and second compartments, where it was quickly cut into shorts by the rich solution. The second table shows this period to be one of high zinc consumption.

The low consumption of zinc cannot be credited, even in part, to clean solutions for precipitation, as no means of clarifying is used except the inefficient one of excelsior, while over three-fifths of the solution is not filtered, but is directly decanted from under the foamy tops of Dorr thickeners and Trent agitators. Trouble from muddy solution in the zinc-boxes is rare, but in treating custom ores, the settling varies so greatly that cloudy solutions occur often. A couple of melts have been prolonged half as long again over the usual time for the bullion produced, due to fine slime in the precipitate, yet the zinc consumption is not materially affected. The most pronounced effect is in the increased value in the precipitated solutions.

The average value of the precipitated solution from the wooden or partial precipitation boxes is 0.20 oz. silver and 0.002 oz. gold, or 14c. per ton; the completely precipitated solution is 0.06 oz. silver, with a trace of gold, and except for two days preceding and during the clean-up, it will vary in total values from 1 to 2c. The same pregnant solution feeds both sets of boxes, and has an approximate value of $4.76.

The zinc in the last compartments is often bright red, from a copper coating; the average content of copper in the ore, however, is almost negligible. The copper in the precipitate averages 3.33%, in the slag, 1.2%, and in the bullion, 4.1%. The use of the weaker cyanide solution results in less copper being extracted from the ore. The precipitate averages 70% gold and silver; it contains less than 7% zinc, giving 10% zinc in the slag, and 1.9% in the bullion. This zinc in the precipitate produces almost no visible zinc fume, and there would be no object in attempting its recovery.

The figure of 0.66 oz. troy zinc per ounce of gold and silver is very close to the theoretical, since the precipitation of silver by zinc is presumably 0.6 weight of zinc for one part of silver. This allows 10% excess for mechanical loss of zinc and for copper precipitation, which seems too close a margin. However, since so many separate months check this figure, and the store-house record of 500-lb. rolls is easily counted, I believe it is correct. It is to be noted that the reaction:

$$(1)\quad KAg(CN)_2 + 2KCN + Zn + H_2O = K_2Zn(CN)_4 + Ag + H + KOH,$$

in which only one part of silver is precipitated by 0.6 part zinc is prefaced in Clennell's 'Cyanide Handbook' by the statement that this reaction probably represents the entire effect of precipitation correctly. In this equation the bivalent zinc does not replace two of the univalent silver, as would be the case with a direct replacement of the silver as follows:

$$(2)\quad 2KAg(CN)_2 + Zn = 2Ag + K_2Zn(CN)_4$$

In this case, one of silver would be precipitated by 0.3 part zinc. However, we know that both hydrogen and an alkali are formed during precipitation, which can be explained by the equation:

$$(3)\quad Zn + 4KCN + H_2O = K_2Zn(CN)_4 + 2KOH + H$$

The combined reactions of (2) and (3) give (1); however, this reaction (1) is only advanced as an approximation, and with solutions rich in silver and low in cyanide, it may be possible that reaction (2) is more pronounced, giving greater efficiency for zinc as a precipitant that reaction (1) indicates.

The lowest published figure on zinc-dust is that given by A. H. Jones in the August Bulletin of the A. I. M. E., for the new Belmont mill at Tonopah, a consumption of 0.78 oz. troy per ounce gold and silver recovered, which is considerably lower than the figures given by Mr. Clevenger for a large Mexican mill using 1.1 parts on the complete circuit, and 0.74 part for the incomplete circuit. Since zinc-dust is much more impure than sheet-zinc, and as the figures on dust were based probably on precipitating solutions high in cyanide and alkali, these zinc-dust figures of consumption are very low.

In 1913 the MacNamara mill at Tonopah, precipitating with zinc-thread and using solutions low in cyanide and alkali, recovered 18.75 oz. bullion for 1 lb. of zinc-shaving, or about 0.83 oz. troy zinc per ounce gold and silver. The Tonopah Extension,† when using a low cyanide and alkali solution, recorded one ounce of bullion for 0.06 lb. zinc, which is about 0.93 oz. troy zinc per ounce of bullion. Both plants melted a certain amount of short zinc in order to keep enough zinc in the boxes to get 1 to 3c. precipitated solutions, as they had but one circuit, and both purchased their zinc in the form of zinc-shaving. Both plants precipitated a low quantity of high-grade solution, low in cyanide and alkali. At the West End, having the advantage of their excellent work, with the additional advantage of cutting our own zinc, and having an incomplete as well as complete circuit, we were able to improve upon their results. Undoubtedly, if the figures were made known, many other silver plants using zinc-thread would be found to have closely approached the low consumption of these Tonopah plants.

Often a zeal to lower costs in one department results in higher costs in other departments. The question would arise if the saving in zinc was made at an additional cost for cyanide, or at a loss in extraction. The ore during the six months, May to October inclusive, was worth $16.66 per ton. The consumption of cyanide was 60.8c. per ton of ore, this item being expressed in money due to the use of 100, 120, and 129% cyanide at different times in the last four years. This amounts to about 2.6 lb. of 129% cyanide at 23½c. per pound, which is as low a cost for cyanide as in 1912, when an ore of equal grade was treated. At that time about 13% of the values was removed by concentration, and a 6-lb. KCN and 1-lb. protective NaOH solution was used in the mill. It is the

†*Eng. and Min. Jour.*, Dec. 2, 1911.

same cost for cyanide as given in the annual report of the new Belmont mill for 1914, on the same grade of ore, where 11.5% of the value was recovered by concentration. The Belmont made a gross extraction of 93%, which, after deducting marketing costs and metallic deductions on concentrate and bullion, netted 90%. Extraction at the West End in 1915 has been better than with the higher before the lower cyanide strength, being 92.5%, with a marketing cost of 1.7% for bullion, giving a net extraction of 90.8%. In 1913, the Belmont mill, on a $21.08 ore, made the high gross extraction of 94.45% with a marketing cost of 2.56%, giving 91.9% net. These figures are given for example only, of extraction, marketing costs, and total recoveries, and cannot be directly compared, as ores from the different mines vary enough to give different results under similar conditions. However, the figures given for the West End can be taken as those of an average Tonopah ore, since the mill has treated ores from the West End, Halifax, Merger, Midway, North Star, and Montana mines during 1915.

It is evident that the saving of 50% in the zinc consumption per oz. of fine bullion was obtained without greater cost for cyanide, and with an increased extraction. The latter was because of the mill solutions carrying less impurities, and only 0.03% zinc. This saving was made during the time sheet-zinc reached the high figure of 28c. per lb., f.o.b., Peru, Illinois. It is now at 19c., which is over twice the average price of 1914. At the present time the study of zinc consumption in cyaniding is a profitable field.

Accidents at Metallurgical Plants

In Technical Paper 124 of the U. S. Bureau of Mines, compiled by Albert H. Fay, the above is discussed for the first time by the Bureau. It covers the years 1913 and 1914.

During these two years 119 men were killed, 2285 seriously injured, and 11,046 slightly injured at smelters and mills, representing fatality and injury rates of 1.55, 29.67, and 143.44, respectively, per 1000 men employed. The report includes the returns of 79 smelting-plants in 1913, and 94 in 1914, including copper, lead, and zinc, and quicksilver smelters, as well as refineries. The iron blast-furnaces are not included in the figures given herein. The number of ore-dressing plants reporting in 1913 was 311, and in 1914, 484. These represent concentrating plants of copper, lead, and zinc ores, stamp-mills, cyanide-plants, and iron-ore washers.

A request for reports of accidents at metallurgical plants was sent out late in 1914 for the year 1913, and there were a number of companies that did not render reports, the request being the first made by the Bureau for reports of accidents at such plants. A larger number of operators reported for the year 1914 than did for 1913, as indicated above. The total number of men reported employed in the metallurgical plants, both smelters and ore-dressing plants, was 35,549 in 1913 and 41,461 in 1914.

Slight increases in fatality or accident rates in 1914, as compared with 1913, may be apparent rather than real, because of more detailed reports having been made for 1914.

The data given were voluntarily supplied by the officials and managers of the metallurgical companies at the request of the Bureau, there being no law compelling such companies to render a report.

In the ore-dressing plants, machinery was responsible for 25.6% of all fatalities, 28.9% of the serious injuries, and 16.5% of the slight injuries. Similar figures for smelting-plants are much smaller, for the reason that there is more machinery in use in ore-dressing plants than at smelters, and the men are usually in closer contact with the machinery, as, for example, at jigs, tables, stamps, rolls, and crushers. There are many revolving shafts, a large number of which have projecting keys, moving belts, wheels, and cams within the reach of the operator. The machinery at smelting-plants is usually confined to the power-house, where the blowers, engines, and dynamos are placed, and to overhead cranes, most of which are out of reach of the regular employees.

The percentage of accidents due to any one cause is given in the following table:

Cause of accident.	Ore-dressing plants.			Smelting plants.		
	Killed.	Seriously injured.	Slightly injured.	Killed.	Seriously injured.	Slightly injured.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Haulage	12.8	9.6	6.9	25.0	14.0	9.7
Machinery	25.6	28.9	16.5	18.7	9.0	5.7
Falls of persons	15.4	16.0	12.4	20.0	13.8	9.5
Suffocation in ore-bins	7.7	.....	.1	3.7	.2	.1
Flying or falling objects	15.4	16.0	23.8	5.0	14.7	17.1
Electricity	7.7	1.7	1.4	5.0	.6	1.2
Hand tools	.....	5.3	10.5	.....	6.9	10.9
Nails, splinters, etc.	.....	1.1	5.1	.....	.3	2.1
Burns	.....	1.0	1.0	11.3	26.7	20.6
Other causes	15.4	20.4	22.3	11.3	13.8	23.1

The percentage of accidents due to falls of persons and flying and falling objects is 15.4% for each in ore-dressing plants, whereas at the smelters the fatalities due to falls of persons represent 20% of the total, and those due to flying or falling objects represent 5%.

Haulage systems cause 25% of the fatalities at smelting-plants, and about half this at ore-dressing plants. The difference is largely due to the type of material handled and to the larger number of cars in operation around smelter yards than at ore-dressing plants. In many ore-dressing plants the ore is brought to the bins in railroad-cars or aerial-trams, and often there is no other haulage-system in connection with the plants, the tailing usually being disposed of by launders or flumes, whereas at smelting-plants the molten slag is usually handled in slag-cars and the bullion on trucks.

At smelting-plants burns from hot metal, slag, etc., claim the largest percentage of serious and slight injuries, and 11.3% of the fatalities.

Disposal of Flotation Residue

By W. SHELLSHEAR

*Introduction. There are many methods of handling sand and slime from metallurgical operations, but in this article the draining and conveying of waste products from flotation processes will be specially dealt with, the methods given being those in use at the leading flotation plants in Australia.

Draining and Dewatering. It is generally advisable to thoroughly dewater the residue from flotation treatment in order to form a closed circuit of liquor. This maintains constant conditions throughout the plant and avoids waste of oil, which would be carried away by the solution with the tailing. The methods that may be used for this purpose are:

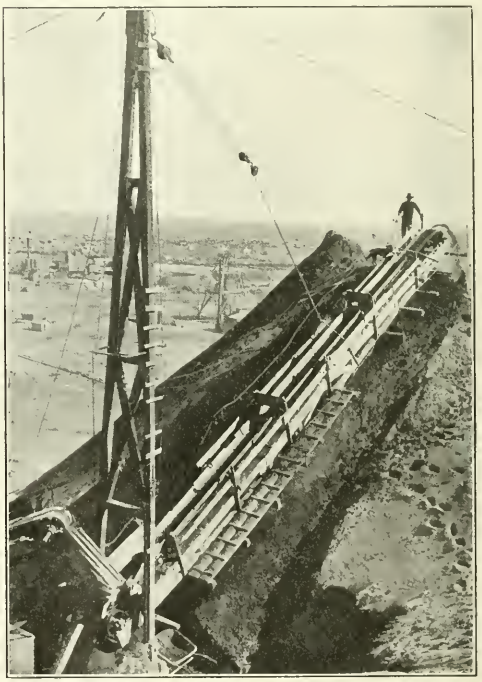
(a) Filtering in vats; (b) combination of a submerged draining-belt and Dorr thickeners; (c) combination of Caldecott diaphragm-cones, draining-belt, and Dorr thickeners, and (d) combination of Dorr classifiers and Dorr thickeners.

Filtering in Vats. In this system, shown in Fig. 1, the pulp from flotation is run direct into vats. These are usually 15 ft. diam., their depth varying from 10 to 20 ft. In the centre of each, and before filling, a tube or pipe, 15-in. diam., that fits over the circular discharge-hole, is inserted. When the vat is ready for emptying, this tube is lifted out, a large proportion of the tailing falling through the centre hole onto a conveyor underneath. The remainder is afterward shoveled upon the same conveyor.

A wooden frame, not shown in the sketch, is erected above the vat to support the lifting-device, a screw-block being used to raise the pipe to the desired height. This operation is afterward carried out by an ordinary block and tackle. The vat may be made of wood or iron, and the height to which it may be constructed is controlled by local conditions, such as the design of the plant, and the nature and fineness of the material to be filtered. It is, however, apparent that the greater the height that can be economically employed, the less the labor required, as a proportionately large amount drops through the centre of the vat without shoveling. This would tend to make the inner tube too long to be handled conveniently, but the difficulty has been overcome by making the tube in sections, each of which is lifted in its turn from the top as emptying proceeds.

The time of filtering is arranged according to the number of vats employed, but it is the usual practice to run the pulp through a number in series, so that the slime settles from the solution. Thus, if six vats are in use, one may be draining and another emptying, while the remainder would be used for the pulp flowing, in series, through them. The filtered water is carried off by a number of pipes at the bottom of each vat. Under certain conditions a suction-pump is connected to these pipes to assist the filtering, but this is not the usual practice. As a filtering medium, cocoa-nut matting is used generally.

After a vat has been emptied, the tube is dropped into



BOOM DISTRIBUTER AT KALGOORLIE, WESTERN AUSTRALIA, 150 FT. ABOVE THE GROUND. BELT-DRIVEN WITHOUT GEAR AT 900 FT. PER MINUTE BY SLOW-SPEED MOTOR CONTROLLED FROM PLANT BELOW. CAN BE MOVED WHILE WORKING.

the discharge-hole, two lugs, one on each side keeping it in position. The open space round the tube is then filled with clay. It is advisable to have the bottom of the vat six feet above the ground-level to allow of easy access to the conveyor underneath. At the spot where the sand is discharged upon the conveyor-belt, guide-doors are arranged parallel with the belt to prevent sand going over its edge, and the number of idlers under the conveyor is increased to prevent it sagging under a rush of feed. The conveyor is usually a flat belt, 24 in. wide, traveling at 350 to 450 ft. per minute, 4-in. iron idlers being used.

This method has many excellent features; its ad-

*Abstract from *Min. and Eng. Review*, Melbourne, Australia.

vantages are: (1) The moisture of the drained tailing is less than in any other system; (2) the slime is drained at the same time as the sand; (3) dams for handling the slime and the cost of labor on same are eliminated; (4) dusting troubles are minimized on the dump, owing to the slime helping to set the tailing; (5) the angle of repose of the dump is increased, thus enabling more sand to be stacked per unit of ground-area; (6) no trouble with conveyors handling tailing will cause a stoppage in the main plant; (7) accurate sampling of products is possible, enabling shift-work to be kept under control.

The disadvantages are: (1) High initial cost of erection; (2) relatively high cost of labor in emptying vats; (3) clarification of solution is not usually as complete as is the case with other methods.

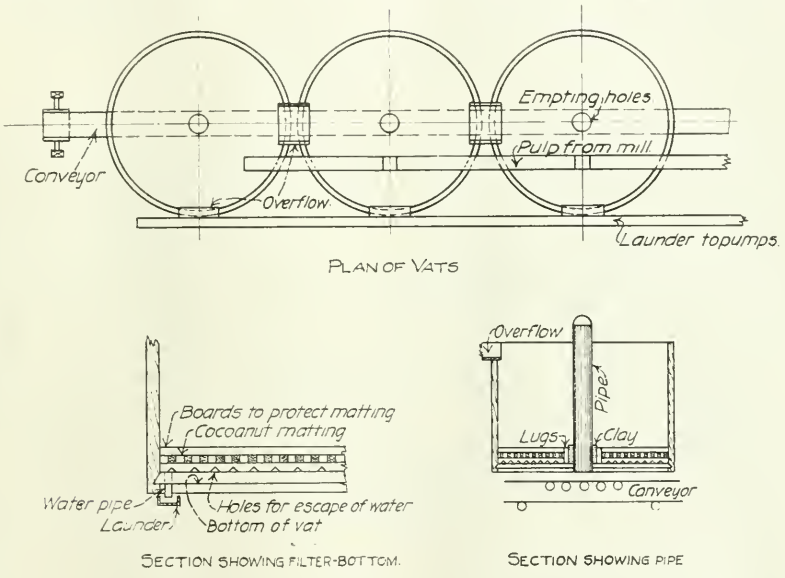


FIG. 1.

COMBINATION OF DRAINING-BELT AND THICKENERS. The idea of the submerged draining-belt, I think, was first introduced in connection with the Elmore process in order to overcome the difficulty of discharging the residual pulp without upsetting the vacuum in the flotation apparatus. In this system the belt runs inside an iron trough filled with water, being forced into a semicircular shape by means of a spherical pulley, as shown in sketch, Fig. 2. The belt travels under water for a certain distance, rising at a slope of 15 to 20° onto the head pulley.

The drive is usually from the tail-end by means of a worm-wheel on the tail-pulley shafting. This tail-pulley is generally 6 ft. diam., and is faced on the outside with wooden boards to give the belt a better grip. The feed is, preferably, distributed to the belt by means of an iron launder with holes in the bottom, wooden guides being arranged to guard against sand getting between the under side of the belt and the trough. The trough has side launders attached to carry the overflow to Dorr thickeners, the number of the latter depending on general conditions, such as nature of slime, amount of water in circulation, etc. The submerged belt forms an excellent desliming system, by reason of the classification in the trough; its capacity is 4000 or more tons a week of mixed slime and sand. The draining of the sand is accomplished as it rises from the surface of the liquid in the trough to the head pulley.

In order to accelerate this draining action, a bumper is usually employed. This consists of an idler driven by two eccentrics. The vibration caused on the belt by the idler striking it underneath displaces a larger quantity of water from the sand, and thus reduces the proportion of moisture in the final product. An iron scraper is used for removing the tailing from the draining-belt; it may be kept under pressure by means of iron springs. This method is very good, especially where the room available for drainage is limited. It is also convenient where the height of the flotation-plant above the ground is small.

The life of the belt is less than that of an ordinary draining-belt, owing to the heavy pressure of the spherical roller, and the action of the hot circuit-liquors in which the belt is submerged. The labor for attendance is small. This method is at present in use on two of the large flotation plants at Broken Hill.

COMBINATION OF CONES, DRAINING-BELT, AND THICKENERS. This method, diagrammatically illustrated in Fig. 3, has been installed in the latest flotation-plant at Broken Hill. The size of the Caldecott cones usually employed is 12 ft. diam. and 10 ft. deep, the diaphragm being 2 ft. to 2 ft. 6 in. from the bottom of the cone. In most cases a plate-diaphragm is used, but the introduction of an

iron ball to serve the same purpose has been most successful. Where a cone of this type is used as a thickener, rather than as a slime-classifier, more pulp may be thickened, as the height of pulp need not be so finely adjusted. Still, it is customary to keep the level of the sand two feet from the top of the cone, as measured in the centre. The feed usually passes into these cones through a centre of the Callow type.

To remove the thickened pulp continuously and divert it onto the draining-belt, an ordinary plug may be used with advantage, provided coarse rubbish has been removed previously. Another

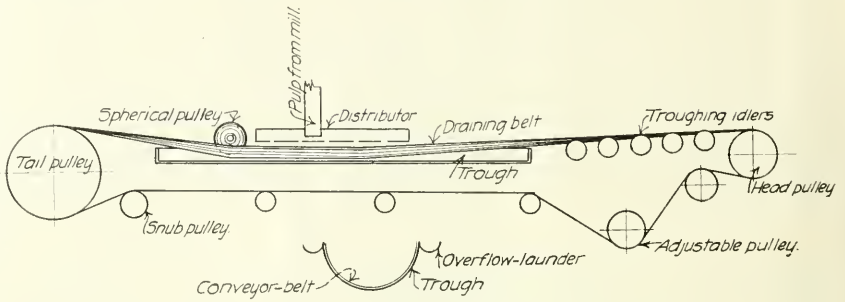

Fig. 2.

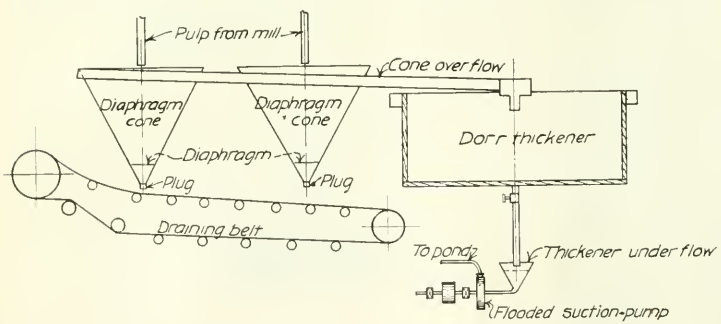

Fig. 3.

successful device is a plug-valve or a plug worked from the top, fitting into a seat at the bottom of the cone. The type of draining-belt employed is 36 in. wide. The belt rises gradually, about 1 in 60, from the tail-pulley, the last 30 ft. of the slope being increased to about 20°. The belt-speed is 20 to 30 ft. per min., both ordinary and troughing idlers, of 6-in. diam., being used. As the operation of the belt is slow, wooden idlers working in cast-iron 'dead-eyes' can be successfully used for the horizontal idlers, the troughing-idlers being of the usual type.

The drive is at the head end, double gearing for speed reduction being employed. The head-pulley is generally 5-ft. diam., the snub-pulley 18-in. diam., and arc of contact 200 to 250°. The tail-pulley is usually 2-ft. diam. Rubber belting on the face of these pulleys reduces the slip, thereby increasing the power-efficiency and the life of the belt.

The overflow from the Caldecott cones goes into one or more Dorr thickeners, according to requirements, the underflow from the thickeners, as in other methods, being handled with flooded suction-pumps. Attempts to mix the underflow from the Dorr thickener with pulp on the draining-belt in order to convey them together to the dump have not so far proved successful. For the control of the underflow from the Dorr thickeners the hydrometer method (described in 'Rand Metallurgical Practice') has proved quite satisfactory, a constant pulp, with Broken Hill slime, of 50% solid being easily maintained. This method is considered a good one, because the cost of labor is low, the life of the draining-belt is prolonged, and the cost of maintenance is small. Adequate headroom is, however, necessary for the erection of the cones;

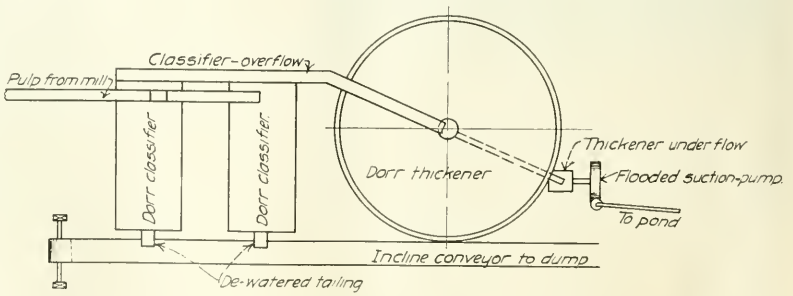

Fig. 4.

in some cases elevation is essential. A disadvantage is that a stoppage of the dump-belts causes a stoppage of the whole plant.

Combination of Classifiers and Thickeners. This method has not, to my knowledge, yet been adopted at

any plant in Australia, but the great success that it has achieved at cyanide plants in America shows that it could be applied to the handling of tailing and slime products at Broken Hill. The usual type of Dorr classifier, however, would have to be specially lengthened to cause extra draining of the sand product. Owing to the regular working of these machines the usual draining-belt may be discarded. At the same time very little head-room would be required. This method is illustrated in Fig. 4, which shows the classifiers delivering direct onto the inclined belt. It has, however, the same disadvantage as the method last mentioned, in that it does not make the treatment-plant independent of the dump-belt stoppages. The cost of erection and maintenance would, however, be small.

Handling of Drained Products. Tailing may be handled in the following ways: (a) Inclined conveyor-belts and boom-stackers, (b) aerial trams, (c) trucking, and (d) sluicing.

Inclined Conveyor-Belts and Boom-Stackers. The usual angle for an inclined conveyor is 20°; where possible the conveyor should be driven from the head-end. Where the head-end is high above the ground, the drive should be either from the tail-end or from a large centre-pulley, midway along the belt, having a snub-pulley at each side above it, the centre-pulley being 6 to 8 ft. diam. and resting, preferably, on a concrete base.

The inclined conveyor is first of all built on trestles at the angle required. As the size of the dump increases, the conveyor is extended in the form of a cantilever, held by guy-ropes from the upright trestles in the dump. A belt to handle 40 to 50 tons per hour would require to be one of 24 in. six-ply rubber built on 3 by 10-in. stringers, placed 3-ft. centres. If driven from the head-end, the driving pulley should be 5 ft. diam. gear-driven, the tail-pulley being 2 ft. diameter.

The Australian practice is to use separate rollers and troughing-idlers instead of a combination idler. This practice is simple; the idlers can be more easily lubricated. The best size of roller is 4 in. diam. It is usually made of steel pipe shrunk onto cast-iron end pieces. A favorite practice is to have idlers and dead-eyes on the top of the same stringers, the loaded and return belt running on rollers supported by the same, and being about three inches apart. The top rollers are usually spaced 4 to 6 ft. centres, the return idlers being spaced at twice this distance apart. Wooden rollers for fast belts of this type are not satisfactory,

In calculating the power required for this type of belt it is well to remember that the horsepower lost in friction per 100 ft. varies inversely as the length of the belt, averaging from 2 to 6 hp. per 100 ft. A tightening arrangement is usually fixed on the tail-pulley of this type of belt to cause it to run true and take up any unnecessary slack. When an inclined conveyor has been carried out to an economical distance, the tailing at its end is made into a bed for a boom-stacker. This is an iron pole, which is held in position by four strong guy-ropes. Attached to the pole is an iron lattice-girder, which is supported similar to a cantilever by guy-ropes attached to the pole itself. This boom-stacker rests on a steel ball in a cup-shaped receiving device, which enables it to swing around as desired. The weight of the boom-stacker is spread over a large area by means of a number of heavy timbers resting in the prepared foundation on the dump. The conveyor on the boom-stacker is driven by a motor fixed behind the boom, and traveling around with it. [The accompanying photograph shows a good boom-stacker at Kalgoorlie, Western Australia, from which place the Broken Hill system was largely copied.—Editor.]

Aerial Trams. These are so well known that they need no description here. For moderate tonnages they are seldom used, as a bin is required and two men loading and operating trucks.

Trucking. This system is followed only in special cases.

Sluicing. There are no features in this method requiring particular mention.

Handling of Slime. The pulp from Dorr thickeners is either transferred by flooded-suction centrifugal pumps or three-throw pumps, or else elevated by an ordinary belt-elevator. Where there is room for a slime-dam close to the treatment-plant, the belt-elevator, which is a very economical system of elevation, may be used. In other cases centrifugal pumps are resorted to. The thickened pulp may also be delivered to dams or sprayed onto the surface of sand-dumps. The banks of the dams are gradually built up by the slime. To remove the drained water it is preferable to use a wooden box-launder. This consists of two box-launders connected in the form of a right angle, and fixed in position at the commencement of the building of the dam. The horizontal portion of the launder is laid about 12 ft. inside the dam, and is carried to the water-sump outside it. The vertical portion passes through the slime and is bored with holes, which are plugged from the bottom upward as the building of the dam proceeds. Probably the best method of handling slime-pulp is to pump it through a nozzle onto the surface of sand-dumps. By such means it may be sprayed evenly all over the dump. This does away with dams, and checks the dust rising from the sand-dump. The idea was first originated in South Africa, and has only lately been introduced into Australia.

Disposal of Australian Lead. Australia produces 10% of the world's lead production, most of it from Broken Hill, New South Wales. In view of recent investigations the following table of the sale of the Broken Hill Proprietary Co.'s ouput should be of interest, by half-years in tons:

Destination.	1913.	1914.	1914.	1915.
Europe	30,606	22,341	13,896	1,100
India, China, and Japan	7,020	12,968	8,432	12,075
Australia and New Zealand	4,686	5,100	5,475	4,337
Vladivostock (Eastern Siberia)	....	.....	.....	1,450
Total	42,312	40,409	27,803	18,962

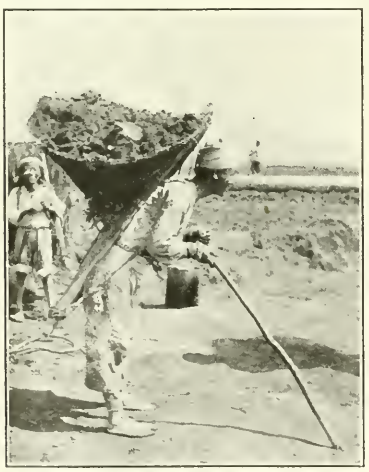
Shipments to Vladivostock were for the Russian government.

Prospecting on the Chiksan Concession

By CHARLES W. DE WITT

The area of the Chiksan Concession is approximately 100,000 acres; it is situated about 60 miles south of Seoul (the largest city in Korea) and 15 miles west of Tsun Po bay on the Yellow Sea. The elevation of the main range of mountains reaches 2000 ft. The majority of the veins lie in this range. The general trend of the mountains is North 60° East, the strike of the principal veins following in the same general direction.

One main fissure has been traced practically the full length of the Concession, a distance of 13 miles; it is on this fissure that the Chiksan Mining Co.'s principal mines are located. Numerous smaller veins are found



COOLIE CARRYING 250 POUNDS.

west of the main range, in the low rolling hills between the mountains and the sea.

The vein material is a medium-hard quartz containing pyrite, galena, and free gold. The country-rock is schist and granite, traversed by dikes of pegmatite. A greenstone of the pyroxene group, dark-brown where oxidized, is found widely over the Concession and in the company's mines at several places. Practically all the veins, large and small, are faulted and cut by dikes at many points, indicating extensive earth-movements.

The native prospectors follow somewhat the same system as the pocket-tracers of California and Oregon, that is, they find the spot in the vein where the best ore is found by repeated panning of the decomposed surface outcrop. When a native has discovered the vein in place, he gets his samples and brings them to the company's assay-office, where all such assaying is done free of charge; if the assays are of sufficient value he is encouraged to continue, and an order is made on the main office to issue him a license to work as a tributer on the Concession.

The prospector will then sink his shaft or drive his adit, as the case may be. Shafts have only one compartment and hoisting is by hand with a windlass. Tunnels are only 4 ft. high by 3 ft. wide. Tramming is accomplished by coolies. As little timbering as possible is done and big chances are taken with caves. However, the same native would not work in a company mine under these same conditions, as he would think it too dangerous. Despite such methods there are exceedingly few accidents, which is probably due to the fact that a

GRINDING WITH A ROCKING-STONE.

Korean has no fear of personal injuries, and will venture where no white man would think of going.

I have seen cases where a miner has fallen down a winze 100 ft. deep and come out with a broken arm and a few bruises; the strange part of it is that there are more fatalities caused from falls of 15 to 25 ft. than from greater heights.

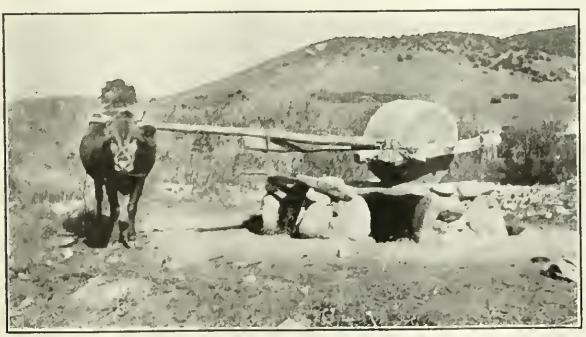
Another method of prospecting is to allow the prospector to work his mine, and pay the company a small amount per man employed. This method has its drawbacks, as one cannot watch them closely; when they pay for one man they will work a dozen; moreover, they will steal powder and drills from the other tributers, which causes trouble among them. The tributers grind the ore by hand or by the use of either the rocking-stone or the rolling-stone. In some places a long distance from the company mill, the Koreans have erected a small 10-stamp

wooden mill, which has a capacity of about two tons per day, when there is plenty of water. This method of prospecting is being discontinued, as neither the prospector nor the company derives any profit therefrom.

None of these small veins has so far proved of any importance, owing to their narrowness; they vary from a few inches to two and three feet in width; the lenses of ore are invariably short, running from 25 to 100 ft. in length, and to a depth of a few feet to 150 ft. for some of the wider veins. Inasmuch as some of these veins are quite rich, the native who finds an ore-lens soon becomes a man of importance; to show his importance he acquires several additional wives; this generally ruins his usefulness to the company, but his success is a great incentive for the others to take the field and look for other rich mines.

The license under which the tributer is working is printed on a piece of wood, 3 by 4 inches, in three languages, Korean, Japanese, and English. This is necessary, as we employ inspectors who go from place to place. The tributer must keep his license with him as his protection, for, should an inspector find him working without the proof of such authorization, everything is confiscated, including the ore mined, and the tributer himself becomes liable to a fine. Japanese and Koreans are used as inspectors, but any member of the foreign staff that happens to pass by may demand to see the license. That is why one side is printed in English. It was found necessary to follow this method in order to prevent prospectors from finding rich spots and carrying off the high-grade to some native grinding-mill, without paying anything to the company.

The ore is carried from the tribute mines to the company mill by means of bulls, both the pack and wagon being used. A bull will pack from 300 to 800 pounds, while the wagons will carry from 1000 to 2000 lb., the driver generally carrying about 50 lb. on his own back.



A ROLLING-STONE GRINDER.

These men receive from 17½ to 20 cents per ton hauled per mile of distance.

Before the ore is shipped to the mill, it is reported to the officer in charge of the prospecting on the Concession; he goes, or sends a trained sampler, to take preliminary grab-samples of the ore to be shipped; if the assays are sufficiently high to warrant treatment in the mill, he authorizes the shipment. A careful sample is then taken at the mill for final assay, on which settlement is made. This settlement is arranged on a sliding

TRIBUTE PROSPECTING.

scale, ranging from 33⅓ to 50% of the gross assay-value.

If a prospector has found a good-sized vein and the ore is not high in value, but sufficient to pay even a small margin over the milling-cost, the prospector is allowed a higher percentage, in the hope of his developing a profitable mine when he gets his workings a little deeper. This larger percentage also applies to prospects that are at a long distance from the company mill, in order to compensate for the long haul. The tributer is also assisted in the furtherance of his work—once he has proved that he has a prospect of any value—by supplies from the company store, where any tools, explosives, and candles will be sold to him at cost, and the amount deducted from his next shipment of ore. This is a great advantage to the natives, as otherwise they could not get explosives at all for small operations, the Japanese government officials being very strict, and all explosives must be carefully accounted for at the end of the month.

On some of the concessions owned by other foreign companies, the prospecting is conducted under a department of the company itself, and their expenditures amount to about $50,000 per year, with little or no ore milled. The Chiksan company has issued 215 licenses, which means that about 200 veins have been uncovered,

leading to the discovery of the main mines of this company; furthermore, the prospecting has been a source of considerable revenue in the past few years, since the tribute system was established.

During the year from July 1914 to July 1915 the tribute-ore milled amounted to 13,680 tons, with a gross assay-value of $86,658, this being purchased from the prospectors for $33,615, the remaining $53,042 being the company's realization.

Under this method of prospecting, and of purchasing the ore from tributers, the natives are thoroughly contented, and are kept ever on the look-out for new prospects. We furnish all the necessary supplies, so that they need not worry while the mine is still unable to produce. By working for themselves in this manner, they feel more independent and above the ordinary coolie class, so that they can get money and credit from their own people. Their finish comes when the mine does not produce as expected and their creditors commence to worry them. At this stage of the game, they generally wait until a very dark night: leaving this part of the country to try their luck elsewhere.

Rock-Drilling Practice on the Rand

*Rock-drilling speed varies nearly inversely as the area of the hole bored, or, in other words, it costs about the same in time and compressed air to excavate one cubic inch of the same rock as another. Are short or long holes more efficient? Disregarding the time lost in starting a hole and adjusting the drill, we find that in the time required to drill one 8-ft. hole (drilling 2 ft. each with steel having bits 2¼, 2, 1¾, and 1½ in. diameter respectively) there can be drilled nearly three 6-ft. holes (drilling 18 in. each with bits 1¾, 1½, 1¼, and 1⅛ in. diameter). By using $\frac{3}{16}$-in. difference in gauge of bits with 18 in. change of steel for the 6-ft. holes, more than three 6-ft. holes can be drilled. Or there could be drilled, in the same time, five 4-ft. holes, starting with a bit of 1⅜ in. and drilling one foot each with 1⅜, 1¼, 1⅛, and 1-in. bits. What is the best length of hole to use; what diameter should be the bottom of the hole; what difference in gauge of bits should be employed; what difference of length in change of steel; what grade of explosive is best for small-diameter holes? Are long holes more wasteful of explosive than short holes? The amount of explosive necessary varies as the square of the burden, so that a hole with a 3-ft. burden requires nine times the explosive charge needed in the hole with a one-foot burden.

Using light water-hammer drills that theoretically can be worked by one native, it was found that the predicted drilling speed could not be realized, so that in practice more natives were required than with piston-drills, principally because the Kaffir can run a simpler machine more efficiently. This does not say that there may not be a design of hammer-drill in existence or in preparation that will not prove to be both a one-man drill and easily supervised.

As to drill-steel, it has been found that hollow steel is harder to sharpen and to temper correctly than solid steel, and in general the use of hollow steel with hammer-drills has proved much more expensive than solid-steel with piston-drills. In very hard ground, the blunting and wear of hollow steel is formidable, and bits are liable to chip away or prove too soft, so that a greater difference of gauge may be necessary than with solid steel. A tremendous importance attaches to having drill-bits true in every particular, so that not only should the shank be in a straight line with the axis of the piston, but the outside edges of the bit should be in a true circle. It is recommended by a skilled investigator that hand-sharpened bits be passed through a proper gauge-circle insuring that each bit be correctly sharpened and gauged. Machine-sharpening has, of course, much remedied these defects.

A blunt drill-bit merely bumps and crushes the rock, powdering its own chippings, instead of cutting the rock and advancing. It is a mistake to use similar drills for boring dry or upward holes as are used in ordinary wet holes. The difficulty of forcing water (with solid drill-steel) into dry holes, ordinarily makes necessary a bigger difference in gauge of successive bits than is required on steel for drilling wet holes. I would recommend for dry holes drill-steel of star section, twisted to form a rotary conveyor to pass cuttings down the hole, with 12-in. difference in length and ⅛ in. difference in gauge instead of the present ¼ in. difference. This should result in drilling upward holes in hard ground in half the time. Also it should make possible the cutting down of the difference in gauge of steel for wet holes to ⅛ or ⅛ in average ground. Such a change would mean that instead of a set of steel being 2¼, 2, 1¾, and 1½ inch for a seven-foot hole, we would use 2 or 1⅞ (starter), 1¾, 1⅝, and 1½ in., which would mean that the amount of ground excavated would be reduced 20% with corresponding increase in drilling speed. For harder ground, a $\frac{3}{16}$-in. difference could be employed, or, better still, the difference in lengths of steel could be cut down to 18 in. with ⅛ in. difference in gauge.

*Abstract of article by T. M. Weston in *The Mining Magazine* for August.

MOLYBDENITE deposits are in much demand at present. Shipments from Lost Creek, 14 miles from Salmo, Nelson mining district, British Columbia, made to the Henry E. Wood company of Denver netted the operators over $800 per car. The vein is 1400 ft. long; the ore varies at different points along the vein, a small quantity running as high as 30% but a good deal of the ore runs around 10%. The ore is said to be amenable to concentration, because containing practically no iron, copper, and metallic impurities that interfere with the successful application of the flotation process for recovering the molybdenite.

Flotation Plant of the Utah Leasing Company

By HERBERT SALINGER

*The new 500-ton plant of the Utah Leasing Co. at Newhouse, Utah, has been built to treat 1,000,000 tons of tailing from the old Cactus mine. The plant is what might be called strictly a flotation unit, as the complete treatment is centred in a Minerals Separation flotation-machine. In this respect it differs from most plants in which flotation is used to help concentration, as at this plant flotation is the sole means of concentrating the ore.

The tailing is taken to the feed-hopper by a drag-line scraper, and from this hopper is raised to the bins by a bucket-elevator. The ore is fed to two 8-ft. by 48-in. Hardinge pebble-mills, with extra large scoops, by means of two Allis-Chalmers Challenge feeders. The Hardinge mills are connected in closed-circuit with two Dorr Simplex classifiers, the minus 65-mesh material being sent to an elevator for delivery to the M. S. machine, and the oversize returned to the Hardinge mills for re-grinding.

Mineral in the tailing is almost exclusively chalcopyrite, but little tarnished. The copper-content, taking into consideration the slime, which averages considerably higher than the sand, is about 0.75% with small gold and silver value. The screen analysis shows:

All through 6-mesh:

Mesh.	%
On 8	5
On 14	25
On 28	28
On 40	18
On 65	6
On 100	5
Through 100	13

Fine material is the richest, that through 60-mesh being approximately 0.95% copper.

The M. S. machine is of the type known as 6–6 combination, being 12 cells arranged in series, six cells of which are of the single-spitz 24-inch standard cells, and six cells being of the double-spitz construction sub-aeration cells, known as the Hibbard cell. Eight hundred cubic feet of air per minute at 5-lb. pressure supplements the agitation in the Hibbard cells, the air being produced by a Roots blower. The M. S. machine is driven from a single line-shafting, the speed of the impellers being 425 to 450 r.p.m. The main body of the machine is entirely built of California redwood. The launders on both the standard and on the sub-aeration section are of the double type.

A concentrate is made in the first three standard cells, to the first of which is also added the feed from the classifiers. The sub-aeration cells make a middling which is returned to the head of the machine for re-cleaning. The concentrate is sent to large bins, of 200-ton capacity, for settling, and the overflow is pumped back to the Hardinge mills. All launders are 14 in. wide and 11 in. deep, the extra size being designed to take care of excessive froth.

Electric power is used exclusively, the power being received from the Beaver River Power Co. at 44,000 volts, which is stepped-down to 2200 and 440 volts respectively in the mill. The Hardinge mills are driven by a 150-hp. type CS Westinghouse motor, connected to a single line-shafting, driving both mills. The M. S. machine is driven by a Westinghouse 75-hp. motor. The drag-line drums are driven by a 35-hp. type K General Electric motor.

The enterprise is too new to afford data for ultimate practice. At present it is found that a mixture of light coal-tar creosote, Barrett No. 4, combined with kerosene acid-sludge from Nicols, California, has given the best results. Good work has also been done with crude wood-creosote, and the addition of a small amount of pine-oil and sulphuric acid. In general, however, the best results have been obtained in an alkaline solution rather than in an acid solution. Complete tests indicate that an average extraction of 80 to 85% is practicable. Almost all reagents are added to the Hardinge mills so as to get the benefit of the resultant mixing action. A small part of the reagents, however, are added at the head of the standard cell.

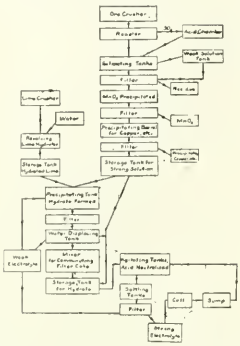
The officers and directors of the company are John H. Leavell, president; J. C. Dick, vice-president; D. R. Pingree, secretary and treasurer, and these, with F. W. Royer and Vivian P. Strange, complete the directorate. The superintendent at Newhouse is Harry H. Adams, formerly of the Stewart mine at Wallace, Idaho.

*Abstract from *The Salt Lake Mining Review.*

GOLD PRODUCED by mines in the United States during the past 18 years totaled $1,531,000,000 or an average of $85,000,000 per year. During the same period the excess of imports of gold over exports amounted to $12,000,000 per year, so that the absorption of gold by the country appears to have been practically $100,000,000 per year, after allowing for the gold contained in minor quantity in ores and silver brought into the country for smelting. Of course recent shipments of gold from Europe have amounted to more than $100,000,000 in a few weeks, but the occasion has been abnormal. It has been estimated that the United States absorbs a quarter of the world's production of gold, which has been about $460,000,000 per year during the past three years. An unknown quantity is taken from the country by travelers to Europe and by returned immigrants. It is not, however, an American trait to accumulate gold, as it is, for instance with the French.

Recent Patents

1,154,602.—Hydrometallurgy of Zinc. Otto Best, San Francisco, California. Filed March 26, 1913.

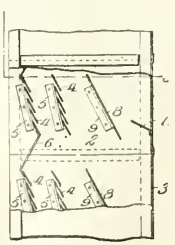


1. In the recovery of zinc from ores and other materials containing the same in an acid-soluble form, the method of obtaining a solution which comprises extracting the zinc with sulfuric acid, and treating the resulting solution before separation from the undissolved material with lime in amount insufficient to precipitate the zinc; substantially as described.

1,154,981.—Tube-Mill. William Fennell, Southam, near Rugby, England. Filed Apr. 25, 1913, Serial No. 763,524. Renewed June 2, 1915.

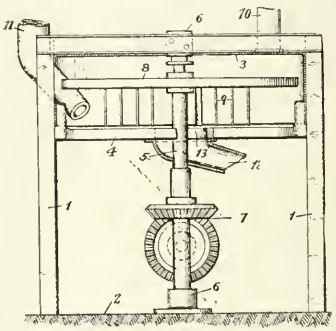
1. The combination with a tube mill of a large number of loose freely movable grinding bodies each made of a length that is equal to a fraction only of the radius of the mill but is of greater length than diameter and has an open ended passage extending lengthwise therethrough and a hole in its peripheral surface of less width than that of the surface adjacent to said hole, substantially as and for the purposes set forth.

1,155,292.—Ore-Separator. Edward Torrey, Thetford Mines, Quebec, Canada. Filed Aug. 9, 1912.



1. An ore separator comprising a chute having two or more rebound devices disposed laterally across the chute, each of such devices comprising a plurality of plates arranged in louver formation; and means disposed laterally beyond such devices for separating the material rebounding therefrom from the remainder of the ore.

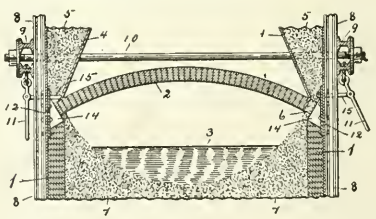
1,149,264.—Cooling Ore. William H. Hubbard, Jr., Salida, Colo., assignor to The Ohio & Colorado Smelting & Refining Co.,



Denver, Colo., a Corporation of Colorado. Filed Nov. 30, 1912.

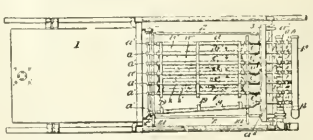
1. In apparatus for cooling hot ore or the like, the combination with a flat circular cooling table for supporting the ore in a comparatively thin layer, means for charging the ore onto the table, means for discharging the ore from the table, rabbles for rabbling the ore on the table and for effecting movement of the ore from the place of charge to the place of discharge; a hood inclosing said table and rabbles, a stack at the top of said hood to conduct the dust and gases away from said rabbles and to insure a circulation of air for progressively cooling the ore on the table during its movement from the place of charge to the place of discharge; substantially as described.

1,149,495.—Metallurgical Furnace. George Campbell Carson, Denver, Colo. Filed Jan. 15, 1907.



In a metallurgical furnace having receptacles arranged above the roof thereof, passages from said receptacles leading to said furnaces arranged in such a manner that the material in said receptacles passes out into said furnaces by gravity and form the lining thereof.

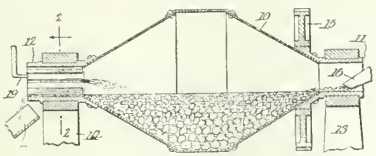
1,158,056.—Filtering Apparatus. David J. Kelly, Salt Lake City, Utah, assignor to Kelly Filter Press Company, Salt Lake City, Utah, a corporation of Utah. Filed October 22, 1913.



1. A filtering apparatus of the open-leaf type having in combination a pressure tank, a carrier removably contained there-

in and adapted to be surrounded by the contents thereof, said carrier being provided with a plurality of filtering elements arranged in spaced relation and between the opposed surfaces of which a solid cake of deposited material is adapted to be built, each of said filtering elements being subjected to the common pressure of said tank, and means for admitting a wash solution to the interior of alternate of said filtering elements, whereby values retained in the cakes are displaced and conducted by the wash solution into the interior of the intermediate filtering elements.

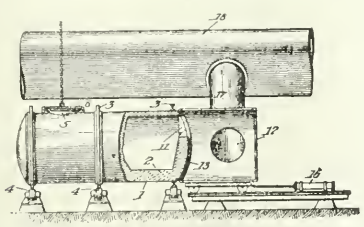
1,149,826.—Sizing Apparatus. Harry W. Hardinge, New York, N. Y., assignor to Hardinge Conical Mill Company, New York, N. Y., a Corporation of New York. Filed Dec. 23, 1914.



1. In an apparatus for the purpose set forth, a rotary tubular outlet member for the outflow of disintegrated material, having on its inner surface a plurality of channels extending in a generally longitudinal direction, and means above the outflowing material for discharging fluid into the channels in a direction opposite to that of the outflowing material.

2. In an apparatus for the purpose set forth, a rotary tubular outlet member for the outflow of disintegrated material having on its inner surface a plurality of channels extending in a generally longitudinal direction, and a jet pipe arranged to discharge fluid inwardly into the channels above the surface of the material flowing out through said tubular member as the latter rotates.

1,153,921.—Converter for Treating Matte.—William H. Howard, Garfield, Utah. Filed Mar. 2, 1914.



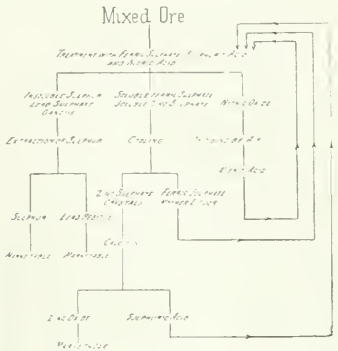
1. A converter for treating molten metal which comprises a horizontal cylindrical shell mounted to rotate on its horizontal axis and having its discharge opening for smoke and gases in one end near its upper side and eccentric to its axis, and a stationary hood into which said opening discharges.

2. A converter for treating molten metal which comprises a horizontal cylindrical shell mounted to rotate on its horizontal axis and having its discharge opening for smoke and gases in one end near its upper side and eccentric to its axis, in combination with a cylindrical stationary hood concentric with said shell and inclosing said opening at all positions of the shell.

1,148,814. Metallurgy of Copper. Lawrence Addicks, Perth Amboy, and Clarence L. Brower, Chrome, New Jersey. Filed August 9, 1913.

1. The refining of nearly pure copper by simple melting under non-reducing conditions and in the presence of only sufficient acid material to slag off the small proportion of impurities contained while minimizing the formation of slag by avoiding contact with acid lining material, and subsequently poling out the small proportion of cuprous oxide incidentally formed.

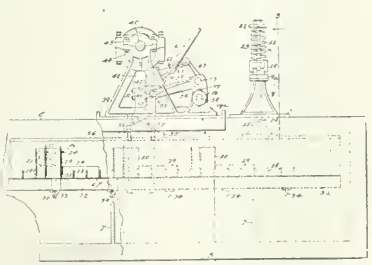
1,157,153.—Process for the Industrial Separation of Lead and Zinc Contained in the State of Sulfids in Ores. Guy de Bechi, London, England. Filed March 29, 1913.



1. A process for the industrial separation of lead and zinc contained in the state of sulfids in ores consisting in reducing the ore to an impalpable powder, treating said powder by a mixture of ferric sulfate, sulfuric acid and nitric acid, whereby the sulfids are transformed into sulfates with formation of free sulfur, and separating the zinc solution from the lead sulfate by filtration.

2. A process for the industrial separation of lead and zinc contained in the state of sulfids in ores, consisting in reducing the ore to an impalpable powder, treating said powder by a mixture of ferric sulfate, sulfuric acid and nitric acid, whereby the sulfids are transformed into sulfates with formation of free sulfur, separating the zinc sulfate from the lead sulfate by filtration, and regenerating the sulfuric acid of the zinc sulfate.

1,159,295.—Jig. Walter T. Tower and Peter D. Camphuis, Wallace, Idaho. Filed July 28, 1914.



1. An ore jig, comprising a tank, a jig screen therein, means for oscillating the same, a plurality of spaced plates arranged transversely therein to retain ore therebetween to form a bed of ore, a cup in said screen consisting of a casing open at top and bottom and having an opening in the lower part of the front thereof, an adjustable gate for controlling the height of the upper edge of said opening, a partition in said cup arranged transversely thereof and provided with an opening intermediate the height thereof, an adjustable gate for controlling the height of the lower edge of said partition opening, and diagonally inclined overflow plates of greater height than said transverse plates leading from the walls of said screen to said cup to direct ore to the opening in the front thereof.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WASHINGTON, D. C.

Rescue and Experimental Stations.—Mining Laws.—Radium-Bearing Areas.—Leasing Mineral Lands.

It is the determination of those in Congress responsible for mining legislation to procure affirmative action on the various proposals, which, with the exception of the bill for rescue-stations and mining experimental-stations, failed to pass in the last short session, chiefly because of the congestion of business. In the Senate, Senator Walsh of Montana continues at the head of the committee on mining, while Representative Foster of Illinois is at the head of the similar committee of the House. Both have been for some time identified with these committees, and both have declared anew their zeal in favor of action on such mining legislation as has been proposed. Already the proper bills are being drafted for introduction. In the main they will follow the bills introduced and discussed in the last Congress.

The chief legislation is to address itself to the enactment of the bill creating a commission to codify the mining laws of the country. It was hoped to procure the passage of this bill in the last session, and while such a bill passed the Senate, a similar bill failed in the House, where, however, it got as far as the calendar. There was one important difference: that of the Senate proposed an appropriation of $25,000 to defray the expense of the commission, while that of the House omitted this provision. The House felt the impulse of economy, and allowed the bill to die. It would, of course, be ridiculous to create so important a commission without means to defray its expenses. The mining men in the House are determined this winter that their bill shall carry an appropriation. It is the plan of Mr. Foster to introduce a bill to the foregoing effect at once, induce committee action with all speed, and so have the bill placed on the calendar of the House near the top for early consideration. The bill had some opposition aside from the appropriations committee of the House. It is planned to have a thorough codification of the mining laws on the Federal statutes, but there are some who think it would be a grave mistake to touch the apex laws, the belief being that it would be well to leave these laws alone inasmuch as the courts have thoroughly established the law and the practice relative to apex mining, and that to inject a change in them would be provocative of fresh litigation and confusion.

Congress is to have the benefit of mining men themselves through the special committee appointed by the American Mining Congress, of which E. B. Kirby, of St. Louis, is the chairman. This committee has made a report in which it is pointed out that the present laws were framed in 1872, and are 40 years behind the times. "They have," says the committee report, "never conformed to the facts of geological structure, and are not adapted to present methods of prospecting, developing, or financing mining properties. The widespread dissatisfaction of the mining public with them has long been expressed through every means at its command." The report declares that the forces back of the revision movement have steadily grown in strength, and that at last the American Institute of Mining Engineers is now free to devote its energies to the cause. In view of the fact that it has been stated in Congress that some engineers have been opposed to apex changes, this last circumstance is important. A preliminary draft of a suggested bill has been placed before the proper committees of Congress and this bill provides that the President shall appoint within 60 days after the passage of the bill a commission of five members of recognized knowledge and experience in the mining industry, which shall give hearings and make recommendations in the form of a fully drafted mining code, reporting to the President within six months, and that the President shall transmit it within 30 days to Congress with his further recommendations, if any. The bill provides additionally that the members of the commission shall have *per diem* expenses. It is the opinion of some mining members of Congress that such a commission should be able to do its work in 60 days after being named, and that if such expedition can be procured the codification can be made law at this session of Congress, which is expected to last well into the summer, if not into the autumn. The committee of the Mining Congress is to have a meeting in Washington, beginning December 16, and it is expected much energy will be expended to procure the passage of this codification.

The radium bills are to be pressed again. These contemplate the conservation by the Federal government of public lands bearing radium, into the production of which the Government is to go for a certain period. The bills have been vigorously opposed, and especially in the Senate, out of fear that they would establish a dreaded precedent in Government manufacture. This contention has had great force up to the time the Government set about trying to produce radium, and it was declared that it would be a failure, but since the Government has been able to produce radium at the rate of about $40,000 per gram, a reduction of $80,000 in the price, the argument is not feared. The Colorado senators, however, dread a vast withdrawal of Government land in their State for radium production, and they do not want any more lands withdrawn from the uses of the people. They are expected to fight the bills with their accustomed vigor, which, however, will be easily overcome should the Senate adopt cloture rules.

The bills for the leasing by the Government of coal and mineral lands now in its possession are again to be pushed. Senator Walsh is most enthusiastic about them. With them goes the proposed legislation for water-power. These so-called conservation bills are backed by the Administration, and in particular by the Interior department. They were discussed a good deal in the last Congress, and failed of passage because of the opposition, which became effective through the jam in all legislation caused by the effort to procure the passage of the Ship Purchase bill.

MONTERREY, MEXICO

Conditions in Nuevo Leon, Durango, Coahuila, and Zacatecas.

While conditions are still very unsettled in the states of Chihuahua, Sonora, Sinaloa, and parts of Durango, quiet prevails in the remainder of the republic, with indications that it may be of some permanency. Considerable quantities of mining machinery are coming in from the United States, and the overhauling of the mills and other general equipment is expected to progress rapidly. The Southern Pacific and other railroads of the United States are now permitting their freight-cars to enter Mexico, and this addition to the equipment of the National Railways of Mexico will enable the more prompt handling of ore between the mines and the smelters, and the

hauling of supplies and other products. The smelters at Monterrey, San Luis Potosi, and Aguas Calientes have ordered large quantities of coke, which will soon begin arriving from the United States.

One of the favorable signs of the improved condition of this part of the country is the re-opening here of several mining company offices that had long been closed. The Compañia Minera de Peñoles brought in a full complement of officials and clerks from the United States a few days ago, and established them in new offices in Monterrey. The mines of this company are situated at Mapimi, state of Durango, and are among the richest in the republic. The working force at the mines is being organized, and it is planned soon to have the property running full time.

The rich copper mines at Jimulco, state of Coahuila, which are owned by a syndicate of San Antonio, Texas, men, headed by Otto Wahrmund, will be operated again in a short time, after a long shut-down.

In the Mazapil and other districts of the state of Zacatecas, mining has been resumed on a considerable scale.

JOPLIN, MISSOURI

Prosperous Conditions Compared with Mining Industry of Year Ago.—Many Mines Change Ownership.—High Recovery from New Picher Plant.—Zinc and Lead Notes.

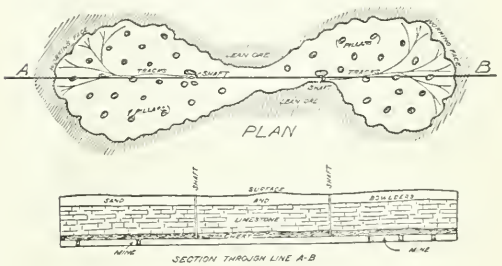
More activity is noted in the Missouri-Kansas-Oklahoma zinc and lead region than at any time in its history; more new concentrating plants are under course of construction than ever before; more mining deals are being consummated; and prices, at the beginning of December, while lacking a few dollars of being up to the record of last August, when a top figure of $135 per ton was reached for zinc concentrate, are more than double those of the corresponding week of 1914. November witnessed the price gradually advance until, at the opening of December, bids ranged from $105 to $115, basis of 60% metallic zinc, for high-grade ores, and from $85 to $105 for second grades. The average basis price of blende for the month of November was $99.35, or almost $20 higher than the average for October, and as a result of the higher basis the majority of operators have increased the wages of their workmen for the ensuing month. Machine-men, who got $3.75 per day in November, will receive $4 throughout December; and helpers, who got $3.25, will now get $3.50. All other workmen receive proportionate increases in wages.

Among recent mining deals, the sale of the Black Hawk and the Lucky Tiger mines at Neck City, Missouri, is important, the price paid for the two properties being $125,000. Formerly owned by G. L. Cole, these two properties now are being operated by the Knight Investment Co., of Utah, and are holding up to their old record of productiveness. The purchasers acquire the first lease on 40 acres on which the two mills, each of which has a capacity of 300 tons per shift, are situated. The Lucky Tiger has been producing for a year or more, but the Black Hawk is a newer property, having been productive for only a few months.

The Providence No. 2 mine and mill, which recently was acquired by E. D. Hornbrook, will soon be producing concentrate. Situated on a lease of the Zinc Corporation of Missouri's land, south of Webb City, Missouri, this mill is the largest in the immediate vicinity. Several years ago the mine was operated by the Yale Mining Co., and later was taken over by the Providence. Owing to an extremely heavy flow of water, mining was abandoned for some time, but the present operators now have their property drained and everything is ready to begin production. The plant is electrically driven and is capable of handling 500 tons of ore per shift. Mining is conducted in sheet-ore at a depth of 190 feet.

St. Louis bankers have acquired the Blue Bird mill and lease of 80 acres of the Cooper land, north of Miami, Oklahoma, for $125,000. The property was owned by the Church & Mabon Mining Co., operators of some of the largest mines in the Oklahoma district. The mine was purchased on its prospects for becoming a producer, rather than for its past record, as the lease had never been placed on a highly productive basis. Although numerous drill-holes showed good ore at from 260 to 300 ft. in depth, Church & Mabon did not sink to this level, but worked an upper shoot which was not profitable. The extremely heavy flow of water encountered in the deeper ground handicapped operations while prices were low, but with present quotations the deeper ground, it is thought, can be worked successfully. The mill is rated at 250 tons' capacity, and it is claimed the orebody has been blocked-out in drilling for a distance of 3000 ft. from north to south. To the north-east is the new mill of the Blue Goose Mining Co., which is now making a large quantity of concentrate from the deeper ore deposits.

An interesting little occurrence, showing how easy it is sometimes for one to stumble onto a fortune, is reported by the Rex Mining & Smelting Co., owning a 1000-acre tract of



SKETCH OF A JOPLIN SHEET-GROUND MINE.

land east of Joplin. Lou Moffett and son, who drove from Arkansas to Joplin in a covered wagon, chanced to camp at a favorite spot on the Rex tract, but unlike scores of other movers who pull in over night and leave next day, Moffett heard of the big money being made in zinc, inquired around regarding the methods of mining, and in the course of a day or so procured the right from the Rex company to cull over some old dumps. He had never seen a piece of zinc ore, to know it, before, but he soon acquired the ability to distinguish the 'pay dirt' from the other, and with the aid of his son made a clean-up the first week that netted $20 each, the most real money Moffett had ever earned in such a short time. The next week he converted his moving wagon into an ore-wagon, hauled many loads of crush rock to a custom-mill, and after six days of diligent toil he sold $496 worth of concentrate. The net profits after the milling bill of over $200 and the royalty had been deducted, aggregated $110 each, $220 between father and son. The old bearded mover and his son had chanced to discover a large 'crush-pile' that had been discarded as worthless by some early day miner who had mined only for the lead, and who had thrown the zinc away. They have enough material to keep them busy for a year or more.

The initial run of Picher mill, No. 1, at Picher, Okla., the newest district, showed the ore to yield 23% blende and galena, remarkable for a hard-ground mine. Elsewhere throughout the district successful operations are being conducted in 2% ore, and seldom is a recovery of better than 3 or 4% recorded. The mill is the first of a series of five to be built immediately, and it has a capacity of 300 tons per shift. Mining begins at a depth of 262 ft., and continues down to 280 ft. Electricity is the power used at the mill.

A company made up chiefly of Chicago suffragists, and known as the Woman's Federal Oil Co., has tackled the biggest drainage scheme in the district, and one which has caused many seasoned operators to get 'cold feet.' They have

leased 493 acres of the United Zinc Co.'s land at Peacock, Missouri, eight miles north-west of Joplin, and four large Texas pumps have been installed to drain the ground to a depth of 150 ft. Ultimately mining will be extended down to 180 ft., where good ore is shown in many drill-holes. The Chicago-Lehigh mill of 300-ton capacity will be moved from Carl Junction, Missouri, a distance of 5 miles. Beginning in 1899, and continuing until about 1908, the Peacock land was a heavy producer. The land lies in a low river valley, and is frequently submerged by flood waters. One of the first steps of the new company will be the construction of a strong dike along the banks of the near-by streams.

KALGOORLIE, WESTERN AUSTRALIA

THE WESTONIA FIELD AND EDNA MAY GROUP.—CHAFFERS AFFAIRS.—PROSPECTING.—SAND QUEEN.—LANCEFIELD.—IVANHOE.—ORE RESERVES.

One of the government geologists, T. Blatchford, has made his preliminary report on the Westonia district, near Southern Cross, and considers that there is no geological reason why the Edna May and Central line of lode should not persist to a considerable depth. The lode consists of a series of lenses and bands of quartz mixed with kaolin and country-rock, with an ususual strike. This varies from north-east, where encased by gneissic rock, to north-west, where the foot-wall is greenstone. The lode thus resembles a hook in shape. The underlie in the gneissic rock is north-west, and at the south-west end in the Edna May is north-east. M. Blatchford points out that narrow granite bars are frequent in the gneissic rock, and in several instances may be seen passing through the lode, but have had practically no effect on it. Since the cross-cut struck water at the 300-ft. level, in July, when the flow was estimated at not less than 750,000 gal. per day, work has been suspended, awaiting the arrival of the three electric pumps ordered. In the meantime a diamond-drill hole put down from the north drive at the 250-ft. level of the Edna May Deeps, passed through the lode at an inclined depth of 208 to 243 ft., calculated to be a vertical depth of 443 ft. from the surface. The bore-hole core from 208 to 216 ft. assayed $2, and from 216 to 243 ft., $30.34 per ton. Where the bore first pierced the lode it was estimated to be only 12 ft. north of the Edna May boundary and 50 ft. from the corner of the Central. The managers of all three mines claim that his own mine receives the greatest benefit, with the result of a wild gamble in all the shares. Deeps, which were $1.44 in the middle of September, were over $5 two weeks later, with wide fluctuations in the interval. Other shares show less advances. Owing to the heavy water encountered, nothing definite is likely to be known this year. The Edna May still continues paying its regular monthly dividend of 72c. per share, making its total $660,000, out of $1,010,000 gold produced in 2½ years.

During the half-year ended April 30, 1915, work was done down to 225 ft. The bottom level is now at 300 ft. Reserves are estimated as 60,100 tons worth a total of $1,300,000. The mill and cyanide-plant treated 17,257 tons and 14,900 tons respectively, yielding a total of 19,738 oz. gold. Six dividends of 72c. each per share were paid. The output in 2½ years is $1,010,000 from 49,572 tons, and $470,000 in dividends. The capital is 50,000 shares at $2.50 each. Costs are $3.46, and development charge, $1.64, a total of $5.10 per ton.

The attempt to re-construct the Chaffers company at Kalgoorlie having failed, the mine and equipment were sold by auction on October 27. The sale is hardly likely to realize sufficient to meet the liabilities. So far as can be learned the mine is worthless down to 2261 ft. Wages owing amount to $8200 since October 18 of 1914, and other creditors nearly $100,000.

Latest reports from the Mt. Holland district are unsatisfactory, and the long looked-for new goldfield seems as far off as ever. The McIntyre prospecting party reached the district recently and will thoroughly investigate it, and then continue on to Phillips river. The season still continues favorable for prospecting, the rainfall in September at Kalgoorlie being 0.18 in., making a total for the year of 16.18 in., against an average of the previous seven years of 8.90 in. for twelve months.

The State's gold output in August was worth $2,145,540, dividends $191,600, making $617,682,500 and $127,180,200 since 1866.

The Sand Queen mine at Comet Vale, owned by Frank Moss, formerly manager of the Kalgurli, and his brothers, is opening well again. The lode at 500 ft. faulted badly, and was broken and worthless; but at 650 ft. it has been found almost similar in characteristics as before. The mine has produced $1,553,700 from 95,300 tons, and paid $510,000 in dividends. For some time past distributions of $15,000 per month have been regularly paid, but it began to look as if this could not be continued. The improvement at 650 ft. has come just in time to save the situation.

George Ridgway, patentee of the Ridgway vacuum-filter, who is now part owner and manager of the Lancefield, 200 miles from here, appears to have at last got the treatment-plant into working order. During August 4660 tons was treated yielding $38,610, and a profit of $10,000; while in September the figures improved to 5448 tons, $46,950 and $15,000 respectively. The mine was formerly controlled by Messrs. Bewick, Moreing & Co., but, though it produced $4,580,000 from 573,000 tons, no dividends were ever earned, and the company collapsed with debts of $200,000. The ore-shoot in the three upper levels is 1200 ft. long and 25 ft. wide, but only returned $5 to $6 per ton. In the sulphide zone the grade is from $8 to $9, but, owing to the presence of arsenical pyrite, costs became prohibitive and extraction erratic, and the venture failed. After examining the mine in company with Richard Hamilton of the Great Boulder at Kalgoorlie, Mr. Ridgway was so satisfied with the mine that he invested his own money in the venture, overhauling and altering the mill. The ore developed is estimated at 250,000 tons worth $8.50 per ton, and this can be materially increased by continuing the drifts in the five lower levels for the full length of the ore-shoot. The deepest level is 1000 ft. on the underlay, which is very flat.

Recent diamond-drilling in the Ivanhoe at Kalgoorlie appears to confirm Malcolm MacLaren's prediction that the lode after passing through the porphyry dike would improve on entering the quartz-dolerite. The first hole cut the lode below the porphyry at a depth of 3457 ft. vertical, where it averaged $7.74 per ton over a width of 78 in.; the second hole reached the lode at 3482 ft. vertical, where it averaged $8.94 per ton and 39 in. The station at 3470 ft. has been made, and a cross-cut east started, so something more definite should be known before long. The sinking of the shaft is to be continued to the next level at 3620 ft., and this depth should be reached early next year.

According to the latest published estimates the ore reserves of the principal mines are as follows:

Name.	Short tons.	Value.	Life of mine, months.
Ivanhoe	1,010,240	$8.82	54
Lancefield	250,000	8.16	42
Menzies Consols	100,000	10.26	40
Horse-Shoe	814,280	7.76	36
Boulder	627,920	13.46	34
Perseverance	595,000	5.76	28
Lake View & Star	426,300	6.42	23
Edna May	60,000	21.08	20
South Kalgurli	165,100	6.12	17
Bullfinch	101,400	6.62	17
Oroya Links	168,600	5.86	14
Corinthian North	62,000	6.72	12
Kalgurli	130,000	...	12
Yuanmi	43,480	9.60	11

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

October returns of the mines on Douglas island are as follows:

	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Stamps working	120	540	270 (now 300)
Ore crushed, tons	19,075	82,593	46,018
Gold by amalgamation	$13,809	$80,358	$36,896
Gold by cyanidation	13,434	74,607	35,403
Total	$27,243	$154,965	$72,299
Average per ton	$1.43	$1.88	$1.56
Net profit after deducting construction	$295	$32,521	$4543*

*Loss.

On November 23, 1000 sq. ft. of the Alaska-Juneau wharf collapsed, dumping 150 tons of coal into the channel. Names of contractors for the new mill were given on page 814 of the last issue of this journal.

ARIZONA

GILA COUNTY

The Iron Cap shaft is down 900 ft., and a station is being cut. The October output was 179,847 lb. of copper, produced at a cost of 9.3c. per lb. The net profit was $15,065, and for six months $85,274.

Caving operations underground at the Inspiration mine are indicated by the openings near the Joe Bush shaft. The surface around this shaft is being prepared in anticipation of a collapse. A dump of ore containing 150,000 tons lying there is to be removed by raises driven up to the surface, and then drawing off the ore to the first level. The direct road between the Inspiration and Miami has been closed on account of the danger of caving. A 95-ton H. K. Porter Co. locomotive was received last week. It is of standard gauge, like the new cars being made. They will carry ore from the mine to the mill.

MARICOPA COUNTY

One of the oldest mining centres of Arizona is situated 15 miles west of Wickenburg, where the Vulture mine was located in 1863 by George Wickenburg. After many troubles an 80-stamp mill was erected in 1881, but the orebody faulted. The property was idle for 20 years, when a Boston syndicate secured control, found the ore-shoot, constructed a mill, and since 1910 has produced gold worth $100,000 per month. About 200 men are employed, and the property is one of the best gold mines in the State.

MOHAVE COUNTY

The new shaft of the United Eastern is down 30 ft. The south drift at 465 ft. is 120 ft. long.——At 505 ft. in the United Western the south-west cross-cut is in 50 feet.

In the Cedar Valley district the American Molybdenum Co. has erected a 25-ton test flotation-plant. At 70 ft. depth the ore contains from 2 to 25% molybdenum.

The property of J. W. Haas at Mineral Park has been sold to E. H. Smith of Phoenix for $50,000. A company will be formed to develop the 300 acres.

Owing to good results in developing a porphyry copper deposit at Mineral Park, a rush has set in to locate claims, and the country between Todd basin and Chloride is all staked. O. A. Turner is developing his deposit, and the ore averages 10% copper. The Copperfield Porphyry Copper Co.'s mine is estimated to contain 100,000 tons of 5% ore.

The United Basin Mining Co. has declared a dividend of 10%, equal to $85,000. Its Golconda zinc mine is employing 265 men.

Large dams are to be constructed at the mouth of Diamond canyon by J. B. Girand to hold water for power purposes. This county lacks cheap power, and this project will be a boon when completed.

YAVAPAI COUNTY

The Tip Top mine, near Prescott, has been a large silver producer, but examinations of its dumps, which contain 120,000 tons, reveal the fact that the waste contains 1.5% tungsten. Underground work has revealed shoots of wolframite, but little notice was taken of them. The present mill can produce 600 to 800 lb. of concentrate per day, but a larger plant has been ordered. Silver ore also remains in the mine and dumps as a chloride, but present efforts will be to recover the tungsten content.

The hübnerite discovery in the Eureka district is attracting attention. One shipment to Pittsburg, 3555 lb., was settled for at $1.60 per pound.

ARKANSAS

The high prices paid for zinc ore in the producing region of this State are said to be so attractive that farmers are taking to mining. This may result in a shortage of labor for farming.

CALIFORNIA

BUTTE COUNTY

The Forbestown Consolidated Mines property was sold last week by F. J. Stoer and Mrs. M. J. Cooney to C. W. Reece of Salt Lake City for $270,000. Payment extends to 1919. The claims are old producers, and are said to contain a large quantity of ore.

Five miles from Oroville the Butte Gold Mining Co. is preparing to resume extensive operations at its claims. A compressor, machine-drills, and 25-ton mill have been ordered. Los Angeles people are interested.

There is considerable activity at the South Banner.

A large amount of work has been done at the Robber's Roost mine at Nimshew, and returns from the gravel are good.

ELDORADO COUNTY

Supplies are being hauled to the Georgia Slide mine near Georgetown, which is bonded to R. E. Cranston and others of San Francisco. Preparations for extensive work are in hand.

INYO COUNTY

(Special Correspondence.)—The antimony mine of the Western Metals Co. at Wild Rose is shipping six tons of ore per day. Labor is done by Mexicans working on contract.

Production at the Skidoo Mines Co. has been interrupted by a scarcity of miners. The minimum wage is $4. The cyanide-plant is being completely housed and insulated with paper.

Skidoo, December 1.

NEVADA COUNTY

Following a preliminary statement of A. B. Foote of the North Star Mines Co., that certain wages were to be raised,

The managers of mines in the Grass Valley district held a conference, resulting in the announcement that the minimum wage of underground men was to be increased from $2.25 to $2.50 per day, and many receiving $2.50 will get $2.75. The companies agreeing are the North Star, Empire, and Golden Center.

The Mayflower mill is crushing ore again, having been closed for a long time. C. E. Brackett is in charge.

At the Golden Center the new hoist is working well. An increase of 10 stamps is contemplated, also a cyanide-plant. At a depth of 180 ft. below No. 7 level a rich shoot was cut last week.

Plumas County

The mill at the Engels copper mine has been doubled in capacity. On account of the road between Keddie on the Western Pacific, and the mine, haulage of supplies and concentrate is being done by teams instead of motor-trucks.

Sierra County

The new stamp-mill at the Oriental mine at Alleghany is working well, with plenty of ore in reserve. Two concentrators are part of the plant.

Tuolumne County

(Special Correspondence.)—The Black Oak mine and mill are working steadily with a full force. Pockets are being put in the main shaft at No. 18 level, which is 1640 ft. from the surface. From this level a cross-cut has been driven to the west, and a drift driven north 130 ft., in which distance some good ore has been encountered. It is necessary to extend this drift 75 ft. before cutting the main shoot. Winze No. 545, out 545 ft. from shaft, from No. 10 level south is down 70 ft. The vein shows 27 in. of $27 ore. On same shoot, No. 13 level south, raise No. 520 is up 150 ft., leaving 100 ft. to excavate to connect winze and raise. The top of the raise shows 4 ft. of $8 ore. All work in south part of mine is in virgin ground, and indications unmistakably ensure that the production will equal that of the north portion.

The Black Warrior mine, a location of 1856, situated on the Longeway ranch, six miles east of Sonora, is being worked by its owners, J. F. Burns and Albert Lund. Free-milling ore is being stoped from the face of a 300-ft. adit, where the vein is 8 ft. wide, and crushed in a two-stamp mill. The owners are making better than wages.

The Monarch Gravel Mining Co., recently incorporated, has taken over a 40-acre gravel claim on the south fork of the Stanislaus river, and an option on 289 acres of land adjoining. A 900-ft. adit has been run on the claim to cut the ancient river channel, the bench gravel of which has been exposed. According to borings the adit must be driven 300 ft. farther to intersect the channel. The claim contains an immense deposit of rhyolite tuff, or pipe-clay, which is now being tested by a San Francisco pottery firm.

E. J. and T. J. Conde and Jos. Oneto have bottomed an ancient channel by means of a 60-ft. shaft, five miles east of Sonora. They found 11 ft. of gravel resting on the bed-rock which gives a coarse gold prospect of encouraging value. Drifts are being driven to determine the extent and value of the gravel.

The company owning the Delmonte mine at Groveland has a representative on the ground making preliminary arrangements for the resumption of operations.

Lessees at the Knox & Boyle mine, embraced within the holdings of the Santa Ysabel Co., are making good. Lessees on the Jumper mine have cleaned up over $100,000 in the past year.

The pump-line is being extended in the Dutch mine, and development work is being pushed vigorously. The App to the south and the Sweeney to the north, two mines included in the recent bond given W. J. Loring, will be explored by drifts run from the Dutch shaft.

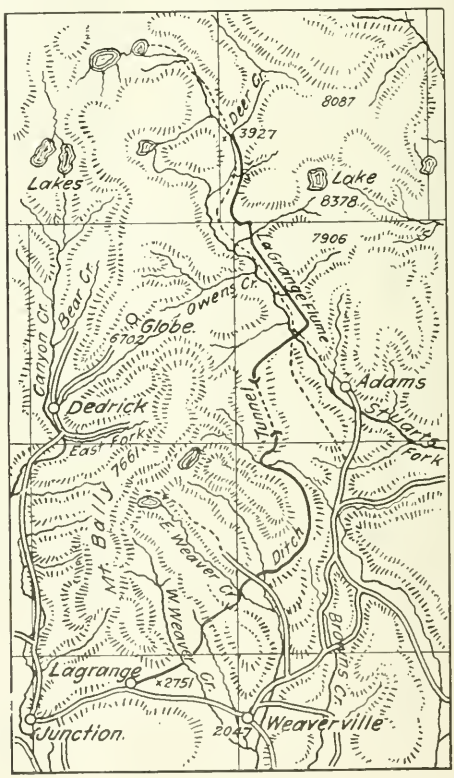
Sonora, November 29.

The Hope 'pocket' mine, near Sonora, yielded nearly $30,000 last month. A lower adit is in 800 ft. to cut the old Tainter shoot, a rich producer. The mine has an air-compressor, machine-drills, and five stamps. G. W. Weston is in charge.

Trinity County

(Special Correspondence.)—An examination of the Globe Consolidated mine, near Dedrick, is being made by San Francisco people who have recently become interested in the company. It is stated more aggressive development work will be commenced, and that improvements may be made to the plant in the spring. The mine has been developed by six adits, and good ore opened. Equipment includes a 20-stamp all-sliming mill, power-plant, and complete mine plant. The mine has produced about $250,000.

The hydraulic mining companies in the Weaverville district



Scale: 1 inch = 4 miles.

MAP SHOWING LAGRANGE WATER SYSTEM, TRINITY COUNTY, CALIFORNIA.

are busily preparing for operations. Late storms piled snow high in the mountains and an abundance of water will soon be available. Flumes and ditches at the Hupp, Lagrange, Testy, and other large properties have been repaired, and large quantities of supplies shipped in.

Vigorous work has started at the Golden Jubilee mine, near Carrville, recently acquired by the California Extraction Co., of San Francisco, for $50,000. New ground will be developed all the winter, to be followed by erection of a plant using a special process for treatment of the base ore. Operations of the mill will be followed with keen interest by local mining

men, as the complex character of these ores has militated against successful working of several properties. Most of the orebodies are oxidized near the surface, but pass into a sulphide zone at varying depths. As many of the mines are within the National Forest, roasting of ores is prohibited because of possible damage to timber by fumes.

Ore ranging from $100 to $300 per ton has been cut in the Lappin mine, near Deadwood. The shoot is narrow, but strong. A new shaft is being sunk and small shipments made to the mill.

Weaverville, November 20.

COLORADO

Clear Creek County

(Special Correspondence.)—The Climax property on Columbia mountain is the scene of a rich discovery, 12 in. of gray copper having been uncovered that is worth $98 per ton in gold, silver, and lead. The shoot is 1450 ft. from the portal of the Learch adit. J. M. Calder of Denver is manager.

The Burroughs mine on Quartz hill is shipping a good deal of $40 gold ore, which is coming from a 5-ft. vein in the east drift run from the Newhouse adit, the shoot showing for a length of 70 ft. N. J. Pike is manager.

E. Mosher, leasing on the East Lake mine on Bellevue mountain, has purchased the interest of his partner, Sam Petrie, paying $5000 in cash. This lease is making $2000 per month net.

Five feet of gray copper ore has been cut on the 400-ft. level of the Oneida property at Freeland that is worth $20 per ton. The ore is under an old stope which yielded $600,000 many years ago. H. T. Rogers of Idaho Springs is manager.

Operations will be resumed at the Gambetta mine on Republican mountain. Development will be centred on the 100-ft. level where a 2-ft. body of 46% zinc is showing. Thos. W. Cunningham of Georgetown is manager.

The Pulaski property on Leavenworth mountain is being developed by W. H. Stevens of Georgetown, and early shipments are promised.

The Mazeppa group of claims on Democrat mountain has been taken over by Jos. T. Broad; development will be continued throughout the winter months.

Idaho Springs, November 22.

There is more work going on in the East Argentine district than for many years, and prospects are good.

Lake County (Leadville)

Owing to an accident at the Penrose shaft of the Down Town mine the motors were submerged, putting them out of commission for a few days. In October the pumps lifted 162,000,000 gallons.

Teller County (Cripple Creek)

The gold output of the district in November was as follows:

	Tons.	Average value.	Gross value.
Golden Cycle, Colorado City	37,500	$20.00	$750,000
Portland, Colorado Springs	11,000	21.50	236,500
Portland, Independence	16,100	3.01	48,461
Portland, Victor	11,400	2.50	28,500
Colburn, Ajax	1,330	6.00	7,980
Caley-J. J. Johnson	1,500	4.00	6,000
Smelters	4,000	55.00	220,000
Total	82,830	$15.66	$1,297,441

On December 20 the Vindicator Consolidated will pay an extra dividend of 3c. per share, equal to $45,000. The company shipped 14,000 tons of ore in November. Development continues very satisfactory.

On December 10 the Golden Cycle company paid its regular monthly dividend of 2c. per share, equal to $30,000.

The ore found in the Gold Sovereign mine last month is proving to be very important. The shoot is from 12 to 18 in. wide, and at the north end assays 266.5 oz., and at the south 11.48 oz. gold per ton. Reject ore shipped was worth $40 to $50.60 per ton. The lessees have opened a stope for 65 ft., with ore still in the face.

Twenty tons of ore from the A. Hickman & Co. lease on Block 160 of the Stratton estate contained 15 oz. per ton. This is the third consignment.

The Cresson company is still sending out guarded shipments of rich ore. On Thanksgiving Day, November 25, two boxcars filled with sacked ore were hauled out for delivery to the Golden Cycle mill.

The Isabella company in November is reported as having produced ore valued at $37,000.

San Miguel County

Concentrate shipments from Telluride for the past 11 months show a large increase over that period of 1914. The November output was as follows in cars:

Tomboy	49
Smuggler	24
Liberty Bell	19
Black Bear	17
Columbia Lease	1
Wagner Lease	1
Total	111

IDAHO

According to R. Macbeth, secretary of the Idaho State Mine Association, there is more activity in Idaho mining regions than ever before. Nearly every idle mine has been re-opened. Contiguous to Boise 100 men are employed, an increase of 900 over this time last year.

Blaine County

During October, the Wilbert company in the Dome district, made a profit of $5578 from the treatment of 1530 tons of 29% lead and 7.45 oz. silver ore. Mining cost $4.19, and treatment $2.25 per ton.

Shoshone County (Coeur d'Alene)

It is probable that the Tamarack & Custer and Ray-Jefferson companies, operating in the Nine-Mile district, will erect a joint 200-ton mill. The former company may declare a dividend of 10c. per share this month, equal to $200,000.

At 4268 ft. from the portal, and a vertical depth of 1400 ft., the vein at the Gertie mine at Burke was cut last week. A large flow of water accompanied the development.

In the Alameda *v.* Success suit for alleged trespassing and wrongful extraction of ore, Judge Woods decided in favor of the plaintiff. The case attracted considerable interest.

MICHIGAN

The Copper Country

The copper output in November was about 25,000,000 lb. The various railways were busy hauling ore all the month, the Mineral Range, Copper Range, and Calumet & Hecla roads breaking records. The Mineral Range line has leased 50 large steel ore-cars from the Duluth, South Shore & Atlantic road, used in carrying iron ore. The Mineral Range hauls ore from over a dozen mines.

MISSOURI

Jasper County

A suit is pending in the Court wherein some hand-jigging syndicates are being sued by farmers who allege that the residue is covering their land.

MONTANA

Lewis and Clark County

There are 200 men working in the Scratch Gravel district. ——The Head mine produced 250 tons in October, but up to

500 tons is expected in November. New machinery has been erected.——Work has been started by J. H. Rowand at the Conrad silver mine, adjoining the Franklin of the Cruse estate.——The Scratch Gravel Gold Mining Co. is producing $2000 per day with 40 men. Above the 200-ft. level there is estimated to be ore worth $1,400,000. The mine is three miles from Helena. W. E. Cullen of Spokane is president.

Silverbow County

Now that the Anaconda company has complete control of the Alice property, it has started overhauling and unwatering with 25 men. The shaft has caved badly. The ore contains zinc and silver. At the Nettie mine the company has unwatered and repaired to 450 ft. At 2200 ft. in its Badger State mine the company has opened a fine body of copper glance.

It is probable that the Butte & Bacorn Copper Co. will be re-organized at Pittsburg. Prospects of the mine being a good zinc producer are considered bright.

NEVADA

Esmeralda County

The Pioneer Consolidated has issued a report in which it is stated that there is a large quantity of good ore opened, and recent development has been very encouraging. The mill is treating ore from three levels. Leasing has been started, the royalty being 10% on all ore less than $50 per ton; 15% from $50 to $75; 20% from $75 to $100, and 25% over $100 per ton. Experiments are being made in flotation. At a depth of 170 ft. a 24-in. vein has been cut assaying $111 per ton.

The Jumbo Extension's Velvet shaft is down 700 ft. The daily output is over 100 tons of ore of good grade.

The Atlanta is sinking through $30 to $35 ore. Improvement is reported from the 1750 ft. level.

The Goldfield Consolidated reports as follows for November:

Ore treated, tons	32,100
Gold extracted	$199,800
Expenses	147,000
Profit	52,800

Humboldt County

An explosion of gasoline resulted in the destruction by fire of the Nevada Short Line round-house and machine-shop at Nenzel. The Rochester Mines Co. reports its silver production for six months ended September 30 as 482,170 oz. In October the mill produced 62,000 oz. and $14,000 gold.

On December 1 the Seven Troughs Coalition company distributed 2½c. per share, equal to $37,500. An extra dividend may be paid for Christmas.

The tungsten mill of the St. Anthony company at Toy is to be enlarged. A high-grade concentrate is made.

Lincoln County

On December 31 the Prince Consolidated at Pioche will pay 5c. per share, equal to $50,000. The daily shipment to Utah smelters is over 350 tons of $7.50 to $10 iron-lead-silver ore. Monthly profits are more than $12,000.

Mineral County

The Eagle Mining Co., at Eagleville, reports that it has settled with the Western Ore Purchasing Co. for 15.5 dry tons of ore assaying 5.63 oz. gold and 3.28 oz. silver per ton, equal to $114.04 per ton gross.

Nye County

At Round Mountain, by allowing its pipe-line to fill with water in 85 minutes, the company is able to sluice for 25 minutes, but when colder weather sets in hydraulicking will cease until spring.

Tonopah mines produced 9747 tons of ore worth $201,406 during the week ended December 4. Development in all of the principal properties continues very gratifying.

White Pine County

The Independent Tungsten Mining Co. has been organized by Duncan MacVichie, W. Armstrong, and T. Giles, of Salt Lake City, and A. D. Myers, W. J. Stewart, and K. C. Davis, of Ely, to develop the scheelite claims located by Myers, Stewart, Davis, and Gaby, just south of Osceola. A mill has been ordered to treat the ore.

A plant to treat 24 tons of scheelite and hübnerite per day is being erected at the Sims-Olsen mine in Spring valley. The ore is mined by open-cut, is wide, and averages 2.5% tungsten. Los Angeles people are in control.

NEW MEXICO

Dona Ana County

(Special Correspondence.)—The Victoria Mining & Smelting Co.'s silver-lead property has been bought by C. T. Boyd of Los Angeles, at sale ordered by the United States district court to satisfy bankruptcy proceedings. The claims comprise about 1000 acres of mineral lands in two groups 20 miles apart, the southern between Organ and San Andres mountains, and the northern in the Plomo district of the San Andres, about 35 miles north-east of Las Cruces. The new owner will start extensive exploration at once. The property contains immense bodies of lead ore of milling grade.

Las Cruces, November 27.

OKLAHOMA

Ottawa County

The Picher Lead Co. has commenced construction on its second 300-ton mill at Picher. It will be driven by electricity.

OREGON

Baker County

A contract was recently let by M. Costello for the driving of several hundred feet in a gravel deposit near Sumpter. This will be part of a new system of mining this material which has been sluiced for some years. F. A. Cowing of San Francisco has an option on the property.

No. 2 dredge of the Powder River company is working just below Sumpter.

The Ben Harrison mine, in the Greenhorn district, has been closed for the winter. Flotation may be used in the mill next spring. Walter Fellows is manager.

SOUTH DAKOTA

Lawrence County

The following notice has been posted at the Homestake mine by the superintendent, Richard Blackstone: "The Homestake Mining Co. will pay to all employees whose names are on the December 1915 pay-roll, additional wages amounting to 7% of the year's salary for 1915. Check for same will be given out on the January pay-days."

Some renewed interest is being taken in the old Germania district, which was a busy place 30 years ago. Prospects are considered encouraging. The Safe Investment, Myrtle, and Lucky Strike mines had a good deal of money spent on them.

UTAH

Piute County

There are 150 men working at the Mineral Products Co.'s mine and potash plant at Marysvale.

Salt Lake County

During November the Salt Lake Stock Exchange traded in 1,335,668 shares valued at $349,693, an increase of $109,662 over that of October.

The Utah Metal & Tunnel Co. has taken over the Bingham New Haven property at Bingham. Shipments are at the rate of 110 to 200 tons per day, respectively. The consolidation will result in better work for both properties. E. P. Jennings and W. H. Barnes manage the Utah, and C. H. Doolittle the Bingham.

The weather has interfered with work in the Alta district,

and ore shipments are almost suspended, although plenty is ready to send out.

SUMMIT COUNTY

The well-known Ontario silver mine at Park City is to be developed on a large scale. There is a good deal of lead-silver ore at 1000 and 1500 ft. A new electric pump will be installed at 1500 ft. in a week or so. There is plenty of ore below this level. Water has been a great drawback. Old stope filling is estimated at 750,000 tons of fair-grade ore. From the old extensive workings the past output is said to be $50,000,000 in silver, lead, and gold, from which $15,000,000 was paid in dividends.

Park City mines shipped a total of 5855 tons of ore in November, making 96,223 tons in 11 months.

The Snake Creek tunnel was extended 360 ft. last month, the heading being at 13,600 ft. The flow of water is 900 gal. per minute.

In addition to its quarterly dividend of 25c. per share, the Daly-Judge is distributing 10c. extra, a total of $105,000. The mine is in excellent condition.

WASHINGTON

STEVENS COUNTY

(Special Correspondence.)—Forty miles north of Spokane the Lafayette Tungsten Co. is operating its property, producing a carload of product every two weeks. This is sent to an electric smelter at Tacoma and converted into ferro-tungsten. A small mill is working at the mine. The head office is at Railway Exchange building, Seattle, with W. H. Lowe as president, and G. Lafayette Loope, vice-president and general manager.

Seattle, December 3.

CANADA

BRITISH COLUMBIA

Dividends paid by provincial mines this year are as follows:

	1915.	1914.	Grand total.
Canadian Consolidated	$468,016	$468,016	$2,291,989
Granby	222,472	448,850	5,438,462
Hedley	300,000	300,000	1,823,520
Le Roi No. 2	59,600	.....	1,625,220
Standard	250,000	475,000	1,800,000
Rambler-Cariboo	35,000	.....	420,000
Total	$1,335,088	$1,691,866	$13,399,191

ONTARIO

The McKinley-Darragh-Savage mines are supplying the mill with 200 tons of ore daily, mostly from the first two. Ten machine-drills are at work underground. Development at 250 ft. is very satisfactory. There are 170 men employed in all. Dividends for 1915 are four of $67,431 each; the total to date being $4,404,459.

From the treatment of 28,600 tons of ore in November the Dome output was $160,000, in addition to $60,000 from the semi-annual clean-up.

YUKON

On November 5 the Canadian Klondyke company's steam-electric plant on Bear creek was destroyed by fire. The pumping-plant inside was surrounded by flames in short time, making it impossible to use it.

MEXICO

SONORA

On December 2 the Rodriguez forces occupied El Tigre. These men are devastating the whole country, and the destruction of the town is expected. They have destroyed 43 bridges between Nacozari and Esqueda. Officials and other employees of the Tigre Mining Co. arrived safely at Douglas. Rodriguez has split from Villa and is acting for himself. He stole 64 sacks of Tigre silver precipitate worth $300 per sack.

PERSONAL

ROSS B. HOFFMANN is at Petrograd.

P. B. MCDONALD is visiting Grass Valley.

PHILIP ARGALL is at Magdalena, New Mexico.

F. LYNWOOD GARRISON is near Tucson, Arizona.

WALTER BEAM, of Denver, is at the St. Francis.

C. W. PURINGTON has returned to London from Siberia.

H. M. PAYNE has returned to London from the Lena region, Siberia.

F. W. GUERNSEY has returned to Trail, B. C., from Thompson, Nevada.

CHARLES A. CHASE has changed his office to 812-824 Cooper Bdg., Denver.

JOHN A. AGNEW visited the Camp Bird mine, at Ouray, Colorado, this week.

NATHAN O. LAWTON, of Lawton, Michigan, will be at New York next week.

JOSEPH G. HIBBS, of Philadelphia, is examining chrome deposits in Del Norte county.

J. D. AUDLEY SMITH has changed his address to Dibbs Chambers, 58 Pitt street, Sydney.

E. E. CAMPBELL is superintendent of mines for the Granby Consolidated Co., at Anyox, B. C.

ANDRE P. GRIFFITHS, manager of the Dos Estrellas, at El Oro, has returned from Mexico to London.

ERNEST B. PEARCE is in charge of the new tin smelter of the A. S. & R. Co. at Newark, New Jersey.

JOHN W. MCKIM, recently with the Blane-Witkop zinc mines in the Transvaal, has returned to Salt Lake City.

W. W. JOHNSON, of the Union Construction Co., San Francisco, recently returned from a successful season in Alaska.

S. C. BULLOCK, formerly connected with the Poderosa Mining Co., Ltd., of Chile, has gone to England to offer his services to the Allies.

ROBERT NYE, of Grass Valley, has been appointed superintendent of the Lincoln Hill Milling & Mining Co.'s property at Rochester, Nevada.

GEORGE H. BARNHART has been appointed manager of the Wanakah Mining Co., Ouray, Colorado, in place of JOHN T. ROBERTS, JR., resigned.

E. K. SOPER, professor of mining at the University of Idaho, has returned to Moscow, Idaho, after several weeks spent in the Coeur d'Alene district, and will leave shortly for Butte.

G. D. HIRSCHBERG and M. N. ZINBERG, engineers on the staff of the Lenskoie (Lena Goldfields) company, in the Bodaibo district of Siberia, are here on a mission to purchase machinery.

W. A. WOLF has resigned his position with the Morococha Mining Co., at Morococha, Peru, to accept the position of mine captain with the South American Development Co., at Zaruma, in Ecuador.

MORTON WEBBER, who left his office at New York to fight with the Allies, has seen service in France (where he was wounded), then on the Gallipoli peninsula, and now "somewhere in the Balkans." He is a lieutenant in the Royal Field Artillery.

J. A. UDDEN, geologist of the Bureau of Economic Geology, University of Texas, has been appointed (October 6, 1915) director of the Bureau, the former director, WM. B. PHILLIPS, having resigned to become president of the Colorado School of Mines.

Some students and two professors from the University of Kansas at Lawrence recently visited the Joplin district, Missouri.

The Southern California section of the A. I. M. E. meets at the Sierra Madre Club on December 14. The feature of the evening will be a valuable paper by Robert T. Hill, of the U. S. Geological Survey, on the geology and mines of southern California.

THE METAL MARKET

METAL PRICES.

San Francisco, December 8.

	Cents per pound.
Antimony	40
Electrolytic copper	20.75
Pig lead	5.50—5.70
Quicksilver (per flask)	$115
Spelter	20
Tin	40
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, December 8.

Antimony: 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica per ton	12
Magnesite: plastic, no iron and lime, calcined, per ton	55
Magnesite: refractory, up to 7% iron, calcined, per ton	30-35
Manganese, 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	$35—40

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 9.—Copper is dull and easy; lead is quiet, though firm; zinc is becoming firmer with more enquiry.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 2	55.50	Oct. 27	48.91
" 3	55.00	Nov. 3	49.37
" 4	55.00	" 10	50.02
" 5 Sunday		" 17	50.46

June	56.43	49.03	Dec.	49.27	....

The silver market has been strong, with sudden movements. The count of metal held in London on November 12 showed only £750,000, against about twice that amount estimated. Indian Bazaars at once commenced buying, also China, along with the English and Continental transactions. The great rise in price followed.

On December 7 silver worth $264,193 left San Francisco for Shanghai. The Nipissing sent 248,306 oz. to London last week, and $393,307 since November 6.

June	13.60	19.75	Dec.	12.75	....

Exports during the week ended November 20 totaled 19,551,362 lb., valued at $3,609,790. England took 4,069,809; France, 7,318,141; Italy, 5,977,122; and Russia, 784,465 lb. Imports amounted to 6,860,191 lb., worth $1,118,474. Canada sent 1,685,046; Chile, 1,237,240; England, 1,826,698; and Peru, 2,002,694 pounds.

The copper production of Michigan in November was much the same as in October, namely, 25,000,000 lb. Calumet & Hecla has declared $15 per share, making $50 for 1915, against $10 in 1914.

United Verde has paid its fifth consecutive dividend of 75c. per share.

The Anaconda output in November was 24,100,000 pounds.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date.		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Date.		Nov. 24	105.00
Nov. 11	100.00	Dec. 1	105.00
" 17	100.00	" 8	115.00

June	30.72	40.26	Dec.	33.60	....

Tin is firm at 37.20 to 37.50 cents.

ANTIMONY

Arrivals in New York will relieve the antimony situation at an early date, inasmuch as shipments are en route both by water from the Far East, and by rail from San Francisco. Meanwhile Chinese and Japanese grades are exceedingly scarce and the quotation is firm at around 40c. The demand is quiet.

ALUMINUM

The sole producer of aluminum, the Aluminum Company of America, is not making any open quotations, and states that it is out of the market, though it is taking care of its regular customers. Odd lots in the hands of dealers and brokers are quoted at 58 to 60c. for metal 98% pure. Less desirable grades are quoted at 57 to 59 cents.

Eastern Metal Market

New York, December 3.

The expected lull in the buying of metal has commenced. It is temporary; but just how long it will last no one can forecast. The London market, which New York has been following rather too closely, according to some people, is weaker. While copper is now quiet, quotations have remained firm, except for the offering of re-sale lots at concessions. Spelter prices have come down with a rush in a demoralized market, about the only feature of which has been pressure to sell. Second-hands show a tendency to shade the quotations for lead. Producers of both copper and lead are in a comfortable position, with plenty of business on their books. The November tin deliveries were small; the total visible supply showed an increase. The shortage in antimony will be relieved at an early date; meanwhile the high price holds. Aluminum is scarce, and practically all new business is confined to lots in the hands of dealers and brokers. Aluminum transmission wire is being sold for re-melting, in view of copper wire being much cheaper.

The shortage of ships is a serious question. At first, ocean-freight space was so difficult to obtain that exporters were chartering vessels. Now they cannot find the vessels to charter, and the foreign trade in metals, as in other products, is being restricted. Russia is doing a vast amount of purchasing in this country, especially in machinery, and is taking more machine-tools, for instance, than either England or France. Buying of finished iron and steel products is being done for deliveries in the third and last quarters of 1916, even though substantial premiums are asked by the mills. Export business in plates, shapes, and bars has been refused at over 2c. per pound. Steel billets for export have been sold at $42 per ton, Liverpool. Pig-iron is advancing, and inquiries are coming out for the second-half of next year. Practically every steel mill has extensions under way or contemplated.

COPPER

The lull in buying which was expected to follow the recent heavy movement is here. It was predicted in last week's report. Just before and just after the Thanksgiving Day holiday the market weakened a little, and quotations dropped to 19.75c. cash, for Lake, and 19.62c. for electrolytic, but there was a quick recovery and quotations mounted to 20 and 19.87c., for Lake and electrolytic, respectively. With the beginning of December, however, prices again declined to 19.75c. for electrolytic and 19.87c. for Lake. It is well understood that the producers are in a comfortable position with deliveries booked for months to come. They can merely look on for several weeks. The lower quotations are not due to any changed attitude on the part of the producers, but to a desire on the part of second-hands to induce business in order that they may realize profits, and to some extent they will achieve their object, as several consumers had made known their willingness to take more metal provided they could buy at ⅛ to ¼c. below the market. Small lots of Lake and electrolytic were offered December 3 at 19.50c. cash. Some good sales on foreign account are yet probable. Custom House returns show that the exports in November totaled 19,393 tons (exclusive of Southern and Pacific ports). Since January 1, 1915, they total 230,146 tons (exclusive of Southern and Pacific ports for November), against 338,063 tons in the same period of 1914. It will be noted that the November exports show a betterment. The London electrolytic market maintains a fairly strong tone. Spot was quoted December 2 at £99, and the 3rd at £98 10s. Figures cabled to the New York Metal Exchange show that the stocks of copper in England and France have continued to decrease. Stocks of all kinds in Great Britain on November 30 totaled 13,572 tons, against 15,473 tons on the 15th, and 18,410 tons on October 31. The stocks of fine copper in France on November 30 totaled 1473 tons, against 1645 tons on the 15th, and 1925 tons on October 31. Of the situation in refined copper, Henry R. Merton & Co., Ltd., London, said, under date of November 12: "The scarcity of freight-room from the States retards dealers here from offering any concessions, and it should be borne in mind that whatever the production of the metal there may be, the question of shipping facilities, or the lack of these, is a factor which is of considerable importance to buyers here." Much interest was aroused a few days ago by the publication in a New York newspaper of a story stating that the Germans had placed orders here for 200,000,000 lb. of copper for delivery after the War. The trade does not doubt that the Teutons have been heavy buyers in this market for later deliveries; in fact, that such purchases were being made was pointed out last spring. When the War started it was agreed that many millions of pounds which Germany had under contract would be held until deliveries could be made, and this, of course, meant after hostilities ceased. The Lake producers, reported a week ago as having withdrawn prices, did not long remain inactive.

Sheet-copper is quoted at about 25c., base. There is an enormous demand for seamless-drawn copper-tubing for the making of shell-rings. All of its makers have increased their facilities, and some firms are reported to have found a way to form the rings out of sheet-copper.

ZINC

In the latter part of last week the market became dull, and since then its bottom seems to have dropped out. Where prices advanced the day previous, they subsequently came down just as fast, or more so, with the result that spot prime Western, which was quoted December 1 at 18.12c., New York, and 18c., St. Louis, came down to 16.75 and 17c., New York, on December 3. January was about 15c. and first quarter of 1916 about 14.50c. The market was so demoralized that prices were not clearly defined, a situation due to offerings by speculators, and even consumers, who sought to dispose of their holdings before it became too late to realize profits. Sheet-zinc was quoted on December 3 at 22c. f.o.b. mill, carload lots. At one time the 8% discount allowed on carloads brought the price of sheets down to, or below, the quotation for zinc. Lower quotations for the metal will again bring the galvanizers into the market. The November exports reached the large total of 9123 tons. On the 30th spot spelter was held in London at £104, but the following day it fell £5 to £99. On December 3, spot at London dropped to £93.

LEAD

The trend in lead has been similar to that in copper. The producers, both large and small, are well sold up and can for a time let quotations stand at 5.25c., New York, 5.17 to 5.20c., St. Louis. These prices have been shaded slightly where it was sought to induce a sale, but on the whole the market has been firm, though dull. London shows a tendency to ease off, despite some important inquiries from Russia. The London quotation for spot on December 2 was £28 15s. Exports in November totaled 5423 tons.

TIN

The November deliveries into consumption were small, amounting to only 2975 tons, but this did not affect the market so adversely as the fact that the total visible supply had increased 3297 tons during the month. The market is dull, almost stagnant, and prices have declined. The spot quotation on December 1 was 39c., and on the 3rd it was 39c. also. The quantity now afloat is 8058 tons. Practically the only interest shown for days has been in small lots of spot tin whose purchase was prompted by necessity.

COMPANY REPORTS

NEVADA WONDER MINING CO.

The ninth annual report of this company, operating at Wonder, Churchill county, Nevada, covers the year ended September 30, 1915. The reports of J. A. Burgess and E. E. Carpenter, for the mine and mill respectively, include the following: Development amounted to 6053 ft., a total decrease of 5052 ft. compared with the previous term. A three-compartment inclined sub-shaft is now being sunk from the 1300-ft. level. A station is being cut at 1450 ft. to connect with workings done from a winze. The cost of mining was $4.16 per ton, a reduction of 49c. The mill treated 58,124 tons of ore, an increase of 9554 tons. The stamp-duty was 15.92 tons per day, or 18.1 tons for actual operating time. The recovery was 95.3% of the gold and 93.68% of the silver, resulting in a total of 9801 oz. gold and 1,123,398 oz. silver. This was an increased recovery of 0.91% in value. The total cost of treatment was $2.813 per ton. All costs amounted to $7.45 per ton, a decrease of $1.49. With cash on hand, $55,231; loans, $220,000, etc., the revenue totaled $561,124. Two dividends of 5% each absorbed $140,808. Cash at the end of September was $10,274.

LAKE VIEW & OROYA EXPLORATION, LTD.

This is an English holding company, having interests in companies operating in Australia, California, Central America, Colombia, and India. The profit for the year ended June 30, 1915, was $173,000, to which was added the previous balance of $120,000, making a total of $293,000. Two dividends absorbed $173,000. The technical committee, consisting of J. A. Agnew, Theodore J. Hoover, J. H. Cordner-James, and A. F. Kuehn, reported as follows on some of the companies:

Lake View & Star mine, Kalgoorlie, Western Australia: Reserves are estimated at 426,301 tons, averaging $6.43 per ton, a decrease of 66,029 tons. Work at 2100 ft. in the Lake View mine is encouraging, while in the Hannans Star mine work has been mainly in the upper portions, above 500 ft.; James shaft is down to 1300 ft. In the six months ended August 31, 1915, the mill treated 108,528 tons for a profit of $96,000. Dividends are equal to 16% on the capital.

Queen of the Hills: This mine is at Meekatharra, Western Australia. It is opened to 524 ft. On No. 5 level the shoot is 135 ft. long, being 59 in. wide, worth $8.30 per ton. Reserves are 37,453 tons of $7.86 ore. A profit of $72,000 resulted from the treatment of 44,055 tons in the year ended June 30, 1915. Sulphide ore is now being successfully treated.

Yuanmi: This mine is in the Murchison district, Western Australia. Down to 680 ft. reserves are 45,562 tons assaying $9.84 per ton. On No. 5 level the shoot is 300 ft. long, with 53 in. width, and $10.80 in value. During the year ended June 30, 1915, the net profit was $38,000 from 43,451 tons, sinking and development being heavy.

Zinc Corporation: This is the well-known company operating the South Blocks mine, a lead concentrating mill and flotation-plant at Broken Hill, New South Wales. The War has affected the scale of operations. Drilling on No. 7 level was very satisfactory, the lode being 40 ft. wide over a length of 350 ft. The mill treated 135,889 tons of ore yielding 27,362 tons of 66% lead concentrate. The flotation-plant is not working on account of the trouble of disposing of the product.

Burma Corporation: This company's property is in Burma, south-east India, where the principal work is at the Bawdwin mine. Ore reserves are 2,000,000 tons, assaying 25 oz. silver, 27% lead, and 22.5% zinc, a large increase. The 100-ton test-plant is busy determining a process. The smelter yielded an average of 1443 tons of hard lead per month. It is to be enlarged.

Central American Mines: This property is in Nicaragua. Owing to re-construction of the treatment plant a loss was shown in the last financial year, but profits are now being made. Anticipated profits are $7200 per month. The total length of ore on the second or lowest level is 1631 ft., worth $12.42 per ton. Reserves total 83,606 tons at $9.28 per ton.

Babilonia Gold Mines: Development shows considerable improvement, and reserves are 30,085 tons worth $9.60 per ton. The old and new plants yielded $105,000. With the new reduction-plant a monthly profit of $4800 is probable.

Granville Mining Co.: This concern controls the Canadian Klondyke Mining Co., now dredging near Dawson, Yukon territory. Up to September 25, the 1915 season's dredging has yielded 48,283 oz. of gold, against 53,775 oz. up to the same date of the year before. The falling off is accounted for not only by the loss of the use of one dredge, but also because of the necessary maneuvering of dredges through accumulated tailing. Next year's work is expected to give much better results. At the annual meeting of the North West Corporation, Ltd., held in July 1915, A. Chester Beatty, the chairman, stated that operations are progressing favorably, and that profits may soon be expected from the washing of gravel on this company's valuable property.

BOOK REVIEWS

EXAMPLES IN MAGNETISM. By F. E. Austin. P. 90. Ill., index. Hanover, New Hampshire, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, $1.10.

Professor Austin is certainly prolific, as this is the fourth book of kindred subjects that we have reviewed recently. This one is for students in physics and engineering. The fundamentals of mechanics, solved examples, and how to apply the results in practice are given. The printing is in green ink, and is not too well done.

METALLURGY. By J. H. Stanshie. P. 151. Ill., index. J. & A. Churchill, London; P. Blakiston's Son & Co., Philadelphia, 1915. For sale by the MINING AND SCIENTIFIC PRESS. Price, $1.40.

The author of this elementary practical work for students and others is connected with several English technical institutions in England, and considers that many students only desire to get enough insight into the properties of the metals in which they are interested, therefore he prepared this book with that object in view, combined with sufficient scope for a course in general metallurgy extending over two years. It might be said that there is little new in the volume, excepting that useful laboratory courses can be arranged for each section of metal workers. The chapters include fuel, refractory materials, formation and reduction of oxides and sulphides, mechanical testing, non-ferrous metals and alloys, iron and steel, and gold and silver (19 pages).

METRO MANUAL. By the engineering staff of the Bausch & Lomb Optical Co. P. 200. Ill., index.

This attractive handbook is published by the Bausch & Lomb Optical Co. of Rochester, New York, and contains technical information regarding construction, adjustment, and use of transits, levels, etc. The firm of Bausch & Lomb has branches at New York, Chicago, Washington, and San Francisco, as well as at Frankfurt, Germany, and London. The handbook contains, besides the standard directions for adjustment and care of surveying instruments, a wealth of useful suggestions and information; for instance, a signal code for gradient work, time and latitude determinations, notes on mining surveys and shaft-plumbing, formulæ, and tables of weights, measures, conversion, etc. Tungsten-steel is used by this company for the making of magnetic needles, because tungsten is tough, strong, and para-magnetic. The problem of the collimation of the central horizontal cross-wire is here discussed fully for the first time. Also deserving mention are: methods of collimation for dumpy-levels; the effect of eccentric centres in transits; and a scientific treatment of the optical question.

ENGINEERING GEOLOGY. Second edition. By Heinrich Ries and Thomas L. Watson. P. 679. Ill., index. John Wiley & Sons, Inc., New York. For sale by the MINING AND SCIENTIFIC PRESS. Price, $4.

The authors are respectively Professor of Economic Geology in Cornell University, and Professor of Economic Geology in the University of Virginia and State Geologist of Virginia. Professor Ries is, of course, well known for his writings on clays and building-stones. This second edition of the book makes the total issue 4000. Only 40 pages are given to ore deposits, and 50 to historical geology. There is much on building-stone, clay, coal, petroleum, and limestone. The chapters on structural and dynamic geology are particularly good; folding and faulting of rocks in their relation to engineering operations, such as tunnelling, are timely points, the importance of which is often overlooked. The chapter on rock-forming minerals is clearly written for the purpose of aiding the engineer in his practical work, as is the portion devoted to rocks. In fact, the manner in which the entire treatment of geology in its different aspects has been kept to the purpose of serving the engineer is commendable. While the book has not been aimed particularly at mining engineers, it is unmistakably a valuable work for engineers in general, representing a maximum of practical knowledge in an interesting manner, with a minimum of inapplicable material.

MACHINE DESIGN. By Albert W. Smith and Guido H. Marx. P. 483. Ill., index. John Wiley & Sons, Inc., New York. For sale by the MINING AND SCIENTIFIC PRESS. Price, $3.

The authors are respectively director of Sibley College Cornell University, and professor of Machine Design in Leland Stanford Junior University. They say "One can never become a machine designer by studying books," and they quote John E. Sweet, who said, "It is comparatively easy to design a good new machine, but it is very hard to design a machine that will be good when it is old."

The present volume is the fourth edition revised and enlarged. Among the chapter headings are: cams; riveted joints; bolts and screws; sliding surfaces; axles, shafts, and spindles; journals, bearings, and lubrication; roller and ball-bearings; couplings and clutches; belts, ropes, brakes, and chains; fly-wheels and pulleys; toothed wheels or gears; springs.

The style is clear and thorough, with a sufficient number of tables, diagrams, and formulæ to make the matter inclusive, but not too many to get in each other's way; altogether a well-arranged treatise of a subject difficult to discuss in its entirety.

DIESEL ENGINES. Marine and Stationary. By A. H. Goldingham. P. 206. Ill., plan, index. Spon & Chamberlain, New York, 1915. For sale by the MINING AND SCIENTIFIC PRESS. Price, $3.

In the Palace of Machinery at the Panama-Pacific Exposition a 500-hp. Diesel engine, direct connected to a 250-kw. generator, was run for 10 months at a cost of 68 cents per hour. Crude California oil was used as fuel for this engine. Since 1892, when the late Rudolph Diesel invented this type of prime-mover, its use has spread to power-plants both on land and sea with success. There are now many manufacturers of Diesel engines, each claiming certain advantages for its particular patented improvements. In the United States there are eight works producing them. Their operation is becoming better understood, and when their low fuel consumption, labor, small area, and output are considered, the engine is without doubt highly efficient. Numerous papers have been prepared on the subject of the Diesel, but this is probably the first time that a practical treatise has been prepared of value to all grades of engineers. All existing literature has been studied and drawn upon, including leading engineering journals, and several well-known makers were consulted. The work is copiously illustrated, the author being able to secure drawings, photographs, and sectional views of nearly all the principal Diesel engines made. Indicator-cards from actual operation are given. The book is really worth while and students and engineers will find it easy to understand the details of construction, operation, and correction, and various types given.

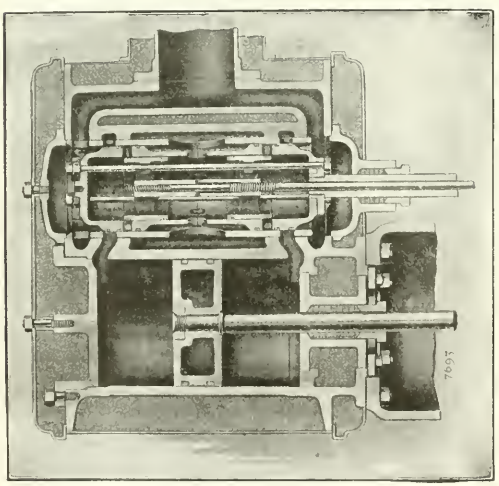
NEW MACHINES AND DEVICES

Information based on letters and catalogues from manufacturers.

Improved Valves for Steam-Driven Compressors

Present day steam-engineering practice is marked by the wider use of high pressure and superheated steam. This condition has made the use of the slide-valve gear, even of the adjustable cut-off type, obsolete practice on steam-driven air-compressors. The slide steam-valve in various forms has been standard on air-compressing units below the sizes (about 24-in. stroke) where the use of the Corliss valve-gear becomes commercially practicable. At high temperature the slide-valve is unsatisfactory, due to its tendency to warp, with consequent leakage. Under these conditions there is also an increasing difficulty of lubrication that results in greater wear and greater force required to drive the valve.

To provide a steam-driven air-compressor which will operate satisfactorily with high pressures and superheat, as well as at



SECTION THROUGH HIGH-PRESSURE STEAM-CYLINDER.

more moderate pressures, there has been developed and perfected a balanced piston steam-valve gear. This has been incorporated in the design of the standard Imperial duplex air-compressors of the Ingersoll-Rand Co., New York.

The use of the balanced valve, it is claimed, makes it possible to control the machine in the only really economical manner, by automatically varying the point of cut-off in the steam-cylinders. This method of regulation maintains constant speed for changing steam pressures and at the same time varies the speed of operation to the demand for air. Steam is always admitted to the steam-cylinder at full boiler pressure, and without the wire drawing of a governor of the throttling type, which means, briefly, that the machine automatically operates at its highest efficiency. It may be mentioned that the higher the steam pressure, the greater the relative increase in efficiency.

With the hand adjusted cut-off valves, usually set at $\frac{1}{8}$ or $\frac{3}{4}$ stroke, steam economy is admittedly poor, while with an automatic cut-off regulation the saving in actual steam consumption is the point most emphasized by the manufacturer.

This piston-valve is a perfectly balanced valve of the telescopic type. The cut-off valve is right and left hand threaded to a cut-off valve stem. Steam admission is through the centre of the valve, the steam passing through the valve-ports to the cylinder, and then being exhausted by the ends of the valve. It should be noted that this construction exposes the valve-chest covers and steam packings to exhaust pressure only, proportionately reducing the liability of leakage. The design and even distribution of metal in the Imperial piston-valve are claimed to preclude any possibility of warping, and to result in a valve so balanced that fraction is minimized and lubrication facilitated.

The steam ports are large and unusually direct, and special effort has been made to reduce the condensation surfaces in the cylinders. Exceptionally complete insulation, the separation of live and exhaust steam-passages, and the fact that the steam-chest partly encircles the cylinder contribute to the steam economy.

The unique steam receiver is a direct connection between high and low-pressure steam-chests. The low-pressure chest is proportioned to furnish additional capacity, and so located that the heat ordinarily lost by radiation is used in heating the cylinder and valve. A special expansion-joint prevents any possibility of cylinder alignment being destroyed.

The governor, automatic and giving close regulation, is a speed and pressure regulator which varies the cut-off by automatically rotating the cut-off valve-stem, and changing the relative position of the cut-off valves. It is a chain-driven rotary oil-pump which acts against a weighted plunger.

The compressor is built in capacities from 608 to 3620 cu. ft. per minute, and for discharge of air pressures from 10 to 110 lb. per square inch.

Commercial Paragraphs

Catalogue No. 12 of the DENVER QUARTZ MILL & CRUSHER CO., Denver, Colorado, contains a large amount of information and data on the well-known type of Chilean mill manufactured by this company. The convex roll running in a concave mortar is claimed to present many advantages over the ordinary type of mill.

Two pamphlets of the DEANE STEAM PUMP CO., Holyoke, Massachusetts, describe its horizontal, single-acting, triplex, portable mine-pumps (pot-valve pattern, 7 by 8 in.); its vertical triplex, pot-valve, outside-packed, plunger mine-station pumps (7 by 12 in.); and its high-pressure hydraulic-power pumps.

In flotation-oil circular No. 9 the PENSACOLA TAR & TURPENTINE CO., of Gull Point, Florida, discusses the rise in prices of pine products; also the subject of 'doped' oils, which many people do not know are sold as the pure product. No. 15, 75, 80, 350, and 1580 are considered good frothers, and ultimately will be used generally.

DENVER FIRE CLAY CO., Denver, Colorado, has published a circular descriptive of the 'Case improved crusher.' The crusher is designed to meet the constantly increasing demand for a strong laboratory ore-crusher, with special emphasis upon its capacity. The folder is illustrated and describes the features and improvements of this new type.

EDITORIAL

T. A. RICKARD, Editor

THE COST of living is increasing; so is the chance of making a living.

FORD and his party have been called 'cranks.' That is an honorable term: the cranks move the machinery of life. The people on the Oscar II are 'self-starters.'

DIAMOND mines in South Africa are to start on January 1, to be operated on a limited scale. This refers particularly to the De Beers, Jagersfontein, and Premier mines.

NOTICE is given by the United States Geological Survey that it is not equipped for making assays or analyses of rocks, its laboratory being overloaded with official work.

SILVER is the basis for international finance between Peking and London, just as gold is between New York and London. Dealers in exchange between Europe and the Far East buy or sell silver as a hedge against their operations.

PERU has adopted the mineral export tax, the bill authorizing the new duties having been passed on November 14. As finally adopted the tax represents a compromise between the demands of the Government and the protests of the mining interests. On metallic copper the export duty is 15 shillings per metric ton when copper is quoted at £60 in London, increasing 2s. per ton for each £1 increase in the quotation.

LOCATION of mining claims is discussed in a timely article by Mr. L. F. S. Holland in this issue. He gives numerous authentic examples of the interpretation of the apex law and the extra-lateral right associated therewith. As the end of the year marks a time of particular activity in the re-location of claims, the information should prove useful. Moreover the eccentricities of judicial decision are suggested in a manner apropos of the effort now being made at Washington to obtain a revision of the law.

COBALT, the use of which is being urged in Canada for the coinage of 5-cent pieces, has a specific gravity of 8.5, which is almost the same as that of nickel. The American 'nickel,' however, is composed of 75% copper and only 25% nickel. Undoubtedly Canada's diminutive silver 5-cent piece is a nuisance. In Germany the lack of metals has caused the Government to issue subsidiary coins made from open-hearth steel. We are informed that recent researches at Queen's University, in Ontario, indicate the possibility of substituting cobalt for nickel in electro-plating. Necessity is the mother of invention; war is the parent of necessity and of other tough progeny.

THAT statement about German buying of copper to the tune of 200,000,000 pounds, for delivery after the War, went the rounds of the daily press without contradiction. We understand that most of the metal agencies have sold copper to Germany for delivery when the trade-route is open again. Some of the copper bought by Germans at low figures early in the War has been re-sold at New York on the advance in price.

MEXICAN affairs are progressing in the right direction. According to the latest advices Maximo Garcia and five other generals of the Villa party have surrendered. Rodriguez and his band have been scattered, many surrendering. Villa's opposition is now negligible. Conditions in the North are improving as the Carranza government extends its control in the wake of the retreating forces of insurrection. Operations have been resumed at Cananea.

COPPER concentration at the Braden mine in Chile is the subject of an article abstracted by us in this issue from the little magazine recently started by the staff of the Braden Copper Company. This interesting publication is called *Teniente Topics* in memory of the *teniente* or Spanish lieutenant who, while escaping from the Argentine into Chile, discovered the first copper vein in the locality and thus was the pioneer of the big operations started in 1906 by Mr. William Braden.

FROZEN ground is an obstacle to placer mining in Siberia, as in the Yukon and Alaska. We give an account of the rudimentary method employed in Russia, where the 'steam-point' is not in general use. The use of hot stones reminds one of the hot iron used in a Russian *samovar* to heat water for tea. Even in the great alluvial operations of the Lena Goldfields the aid of steam in overcoming the perennial frost has only been adopted during recent years, to a minor extent. We are aware that a supply of 'steam-points' is now being purchased for this purpose in San Francisco and Seattle.

RIVALRY between copper and aluminum has been averted by the extraordinary rise in the price of the latter metal, for which 60 cents is now being asked. Indeed, the market for aluminum has risen so greatly as to warrant the dismantling of transmission lines in order to sell the metal. For instance, the aluminum wire of

the Reno Power, Light & Water Company, which serves Virginia City, Nevada, has been removed and sent to San Francisco for shipment to England. In this case the strands were 78 miles long and had been in use 11 years. At the time the line was erected the aluminum cost 32 cents per foot; now it is worth 48 cents per foot. Thefts of aluminum wire indicate its increment of value during the War.

AN action brought by the Goldfield Consolidated Mines Company against the Collector of Internal Revenue to recover $91,890, the amount paid in income-tax in 1909 and 1910, was dismissed on December 1 by the United States District Court in San Francisco. The suit was brought on the ground that the ore taken out of the mine should have been deducted from income, because the removal of the ore depreciated the company's capital and was equivalent to an operating expense. We are glad suit was brought, but action was taken too late. When the first dividend was paid, it should have been claimed as return of capital, until all the original capital had been returned to the shareholders. Now that this splendid mine has amortized its entire capital, the argument has been weakened. Of course, the dividends paid by a mining company are not income until the capital has been redeemed, for a mine is a wasting asset and has no goodwill when it is exhausted. But these are points rarely recognized when a mining enterprise is being incubated.

KNOWLEDGE of geography has been stimulated by the War. Most of us have obtained a better idea of relative distances and international boundaries since the organized calamity began. For instance, Archangel, on the White Sea, has come into prominence as a Russian port of entry since the Baltic was closed by the German fleet and the placing of mines in the Danish straits. But Archangel, despite the use of ice-breakers, is not open throughout the winter, so that an effort has been made to find other means of maritime communication with northern Russia. This has been effected by the construction of a railway to Katerina, in the estuary of the Luta river, on the coast of Lapland. The port of Katerina, or Ekaterina, is free of standing ice all the year round and the danger from Arctic ice-floes is to be minimized by the service of a wireless-telegraphic station. Mining operations in Siberia and the travel of engineers connected with Anglo-American enterprises there will be facilitated by the opening of the new route. Recently they have had to go by way of Tornea, at the head of the Gulf of Bothnia, and earlier in the War by the crossing from Stockholm to Rauma in Finland.

INCOME-TAX and other restrictions due to the War are likely to affect that part of the world's mining business that heretofore has been administered from London. English companies are now under decided disadvantages, some of them so marked as to prompt a change of registry. Those operating in Canada are hastening to place themselves upon the Canadian register. Similar changes are likely to be made in the case of Anglo-American enterprises, for the new income-tax will seem, to anybody but the most patriotic Britisher, an imposition without adequate recompense. Moreover, the scarcity of money for the purpose of mining and the embargo placed by the Treasury on new issues of capital will join in rendering London unpopular to mine operators. Unless, however, the American speculator or investor puts his money into foreign ventures, and on a big scale, it is probable that London will regain most of its ascendancy as a financial centre when the War is over. It is not lack of money, but the opportunity for it and need of it for domestic industry, that has prevented New York from superseding London as a source of capital for mining in a worldwide way. That opportunity and that need will alike continue to exist, and check American exploitation in foreign countries.

The Alaskan Affair

Our esteemed contemporary on Manhattan island, in its interesting issue of the 4th instant, "gets off on the wrong foot" when it states that Mr. F. W. Bradley and his associates operating the Treadwell group were skeptical of the claims made by the Jackling group in regard to what could be done in low-grade gold-mining on the Perseverance-Gastineau lode and of the development of the Alaska Juneau as undertaken by themselves until they became "converted" by the results obtained by their neighbors. The question is not one merely of priority, it goes to the heart of the entire problem. Our readers ought to be well aware of the facts, for they were stated clearly in our issue of December 6, 1913. However, we have added so many new subscribers since that date that it is worth while to re-state the origin of the Juneau enterprise. After an enormous lode of low-grade ore in slate had been proved by the shallow workings of the Juneau, starting from surface in Silver Bow basin, it was planned, as early as 1899, to tap the lode by a low-level adit. This work was begun in 1909, but financial arrangements ensuring the completion of it were not made until August 1910, when Mr. Bradley entered into a contract with the Alaska Juneau company to drive the adit in return for a share-interest. In 1912 Mr. D. C. Jackling appeared on the scene, and looked into the prospects of the adjoining Perseverance property. Undoubtedly he was led to consider the big scheme of development since put into effect by the Alaska Gold Mines, which controls the Alaska Gastineau property, by reason of the work undertaken and the plans formulated by engineers so experienced and capable as Messrs. F. W. Bradley and J. H. Mackenzie. If Mr. Jackling and his associates were influenced by the initiative of "the Treadwell group" they were wise, for no amount of experience in copper suffices to solve the problems peculiar to gold mining. The dissemination of chalcocite in monzonite porphyry exhibits a degree of uniformity in strong contrast with the sporadic distribution of native gold in quartz veins traversing slate. In the Juneau-

Gastineau lode-channel the ore is confined to the quartz stringers, which, by themselves, assay $6 per ton in free gold. The slate traversed by these stringers is practically barren; and so are the meta-gabbro dikes that cross the lode. The gold-bearing solutions appear to have confined their impregnation to the quartz stringers; they did not enrich the enclosing rock sufficiently to render it valuable to the miner. The deposit, as a mine, must be interpreted in terms of the gold in these quartz stringers. The original claim of a $1.50 average, made by the promoters of the Alaska Gold Mines, means mining a width of lode containing 25% of quartz stringers. This can be done, but not at a cost of 75 cents per ton. By careful selection and sorting it is possible to send even $6 ore to the mill, but at a cost entirely prohibitive. It is also possible by indiscriminate mining of lode-matter and quartz stringers to ensure a very low cost per ton, but such mining would reduce the yield of gold so as to render a profit out of the question. On the other hand, during the first four years (1897-1901) of operations at the Juneau an average yield of $4.10 was obtained by sorting 4½ to 1. By selecting the best places and rough sorting in the ratio of 1.6 to 1 in the next nine years (1901-1910) an average of $1.45 was obtained. In a report issued last April, Messrs. Bradley and Mackenzie estimate that, after a given proportion of sorting, an average ore of about $2 per ton can be obtained and that the selection of the ore to this degree will prove the most economic, giving a profit of 70 cents to $1 per ton on a tonnage of 1,500,000 to 2,000,000 per annum. The lode widens in the Juneau to 900 feet, but the ore is largely confined to three widths or bands, which will be mined, leaving the intermediate portions to sustain the ground. Whether the different treatments of the problem, breaking to a $1.25 mill-ore in the one case and to $2 ore in the other, are due entirely to a difference of policy or are modified by a difference in the distribution of the ore within the lode is a question yet to be made clear.

In the same article our contemporary says that "when it is a matter of 50 years' life, a gross of less than 6½% is needed to yield 6% net, which is about the basis on which our great mines sell, whether they ought to or not." Evidently the *Engineering and Mining Journal* does not know whether 6% is, or is not, a sufficient yield from a gold mine. Yet the matter is of some importance to the profession, which is called upon to advise those that put their money into, or take it out of, mining property. As we have indicated, more than once, the yield of 6% on a 50 years' life would be satisfactory if there were any assurance as to the accuracy of that estimate of continuous production, but the fact is that the 50 years is the result of a calculation based on several uncertain factors, of which the most uncertain determines the strength of the whole chain of causation. It is not an assured fact, only a reasonable hope, for instance, that this particular mine in Alaska has a life of 50 years. At the present time of writing the original estimates of yield and cost have been so stultified as to render it quite uncertain what is to be the average grade of the ore to be milled, and until that is determined no estimate of tonnage, and therefore of life, is reliable. Here we see the basic error made by others besides our learned contemporary in ignoring the fact that all estimates of tonnage, yield, cost, and therefore profit, per ton, are approximations. Being only approximations, the business organized on them is subject to risk. This risk calls for a proportionate recompense. In short, risk is an essential part of mining; the proportion of risk involved in any particular case must be gauged by the engineer, and not until he has considered it carefully as a chief part of his problem is he in a position to state what should be the annual yield on the capital involved. Obviously 6½% per annum is too little on a mine the market-value of which, as indicated by the quotation of its shares, has had to be discounted by 50% within six months.

The Status of Flotation Litigation

Our readers will be awaiting with keen interest the decision of the District Court at Wilmington in the case of Minerals Separation *v.* Miami. This probably will be handed down by Judge Bradford before the end of the current month. The final judgment of the Supreme Court of the United States on the review of the decision given by the Court of Appeals in San Francisco in the Hyde case is expected in March. Meanwhile an explanation of the present position of the litigation is timely. It cannot be understood by the layman without a brief reference to the relative positions of the various courts involved in the protracted legal contest between Minerals Separation and those whom it charges with infringement of its patents.

Until about three years ago the United States judicial system, so far as general jurisdiction is concerned, consisted of three courts, the United States District Court, the United States Circuit Court, and the United States Supreme Court. In addition to these three branches there was also a United States Circuit Court of Appeals to which appeals were taken from the decisions of the United States District Court and the United States Circuit Court. The judges sitting in the United States Circuit Court of Appeals were judges of the United States Circuit Court, designated for the purpose of constituting the appeal court. In the course of time it was found that no advantage arose from the existence of two separate United States Courts of original jurisdiction. As above described, the system included two courts in which suits initiated, namely, the District Court and the Circuit Court, the District Court taking cognizance of admiralty and certain other classes of litigation, and the Circuit Court taking cognizance of the other matters arising under United States law. By a recent statute, passed about three years ago, the Circuit Court was abolished and all suits are now originally started in the District Court. From the decisions of the District Court appeal lies to the Circuit Court of Appeals, and in certain cases, may be reviewed by the Supreme Court of the United States.

The Hyde case, which is the suit involving the Butte & Superior company, was started prior to the enactment of the statute abolishing the United States Circuit Court, which at that time was the court of original jurisdiction in patent matters. This statute was enacted while the Hyde suit was pending before the Circuit Court and the passing of it merely had the effect of automatically transferring the case from the abolished United States Circuit Court to the United States District Court, the jurisdiction of which was enlarged to include all cases, as indicated.

In certain classes of litigation the defeated party has the privilege, as a matter of right, to appeal from the decision of the United States Circuit Court of Appeals to the United States Supreme Court, and in such cases the Supreme Court must, under the law, hear and decide the appeal. The volume of business before the Supreme Court, however, became so great, some years ago, that the right of appeal to the Supreme Court, in certain classes of cases, was abolished, patent cases being among those in which litigants no longer have any right of appeal to the Supreme Court. While in the class of cases mentioned the right of appeal has been taken away, the parties still may file a petition in the Supreme Court asking that it review the case, and the Supreme Court, upon inspecting the petition, may, according to its judgment, either review the case or refuse to do so. This petition to the Supreme Court is technically known as a petition for a writ of certiorari, the words signifying that the Supreme Court is asked to direct the lower court—in this instance the Circuit Court of Appeals—to transmit to the Supreme Court a certified copy of the record in order that the latter may review the case.

In patent cases it is quite exceptional for the Supreme Court to grant a writ of certiorari. The United States is divided into nine judicial circuits, each circuit having its distinct system of District Court and Circuit Court of Appeals. It is therefore possible, and it sometimes occurs, that a point is decided one way by the Circuit Court of Appeals of one circuit, and oppositely by the Circuit Court of Appeals of another circuit. In such cases the Supreme Court will always grant a writ of certiorari in order to harmonize the law in the different circuits, but in the absence of some such compelling reason it is quite exceptional for the Supreme Court to grant the petition for writ of certiorari. It is necessary that some exceptional circumstance shall exist. In the Hyde case, now before the Supreme Court, Minerals Separation represented that the decision of the United States Circuit Court of Appeals for the Ninth Circuit was at variance with the decisions made by the House of Lords and by the Privy Council of the British Empire in the suits brought by owners of the Elmore patents against Minerals Separation in one instance, and against the Sulphide Corporation in the other instance. If the Circuit Court of Appeals for the Ninth Circuit had arrived at a conclusion opposite to that of the British House of Lords and the Privy Council of the British Empire there might possibly have been some reason for the Supreme Court of the United States taking the matter under advisement, notwithstanding that the tribunals mentioned are in different countries, this by reason of a certain deference shown by the courts of each country for the decisions made by the courts of the other country. The word 'comity' is the legal term generally employed to designate the weight that one court attaches to decisions of another court, when the decisions are not strictly binding by reason of the superiority of one court to the other.

The Elmore litigation decided by the House of Lords and the Privy Council involved the question whether the operations of Minerals Separation constituted an infringement of Elmore's patents, the Elmore patents in issue being those covering what is generally termed the 'bulk-oil' process, in which immense quantities of oil are used and in which the formation of a froth does not figure. The British courts decided that the operations of Minerals Separation and its licensees do not infringe the Elmore patents. The position of the Miami in this matter is that there is absolutely no conflict between the decision of the Circuit Court of Appeals at San Francisco and the decision of the British courts. Counsel for Miami never maintained that the Elmore bulk-oil patents anticipated the frothing process or that they disclosed the frothing process, or even suggested it. On the contrary, they have maintained the opposite. Minerals Separation, in the Hyde and Miami cases, has made the contention that the Elmore bulk-oil principle was involved in processes disclosed in the Everson patent, the Criley & Everson publication, the Fryer Hill publication, the Froment patents, the Froment description, the Kirby patents, and the article in the *California Journal of Technology*. Miami maintains that the bulk-oil principle was not involved in any of these operations and that it was not involved in any process except that described by the Elmore brothers. The Court of Appeals at San Francisco took the same position, and this position is in strict accord with the decision of the British Courts. If the Court of Appeals at San Francisco had decided that the Minerals Separation patents were anticipated by the Elmore bulk-oil patents, then there would have been a distinct disagreement between that court and the British courts. But such was not the case. In order to weaken the defence, Minerals Separation endeavored to establish identity between the prior art processes cited by the defendant, and the Elmore bulk-oil process. Defendant denied such identity and maintained that the prior art processes were like the Minerals Separation processes and totally different from the Elmore bulk-oil process. It remains now for the Courts to decide. The decision in the Miami case will be appealed, of course, whatever way it goes, but it may not go beyond the Court of Appeals at Philadelphia, because writs *à certiorari* are not often granted. Meanwhile the decision of the Supreme Court in the Hyde case will not be without its influence on the appeal in the Miami case from the Wilmington court. If Minerals Separation loses, the flotation process may be freed from patent litigation—a consummation devoutly to be wished; if it wins, another series of suits is probable.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

A Launder-Sampler

The Editor:

Sir—I am enclosing sketch of a scheme I devised for taking launder-samples in the Suan mill, at Holkol, in Korea. This sampler gave us excellent results, about a dozen being placed in the mill, and I hope that a description will be of benefit to others.

A detailed description is hardly necessary, as the sketch indicates clearly the construction and mode of operation. In reality it amounts to a square slip-joint pipe, lacking one side, the outside dimensions of which are the same as the inside of the launder, the upper section being securely fastened to the launder, while the lower section slides freely on an oakum-packed joint. A section is removed from the bottom of the launder to allow the total pulp to drop through into the sample-tin. The draw-bar is fastened to one section, so as to facilitate removal.

We found no difficulty in placing these samplers while operating. When closed they made an absolutely tight joint; in operation, an accurately timed clean-cut sample is readily obtained for dilution and tonnage calculations.

H. B. Fields.

Holkol, Korea, October 6.

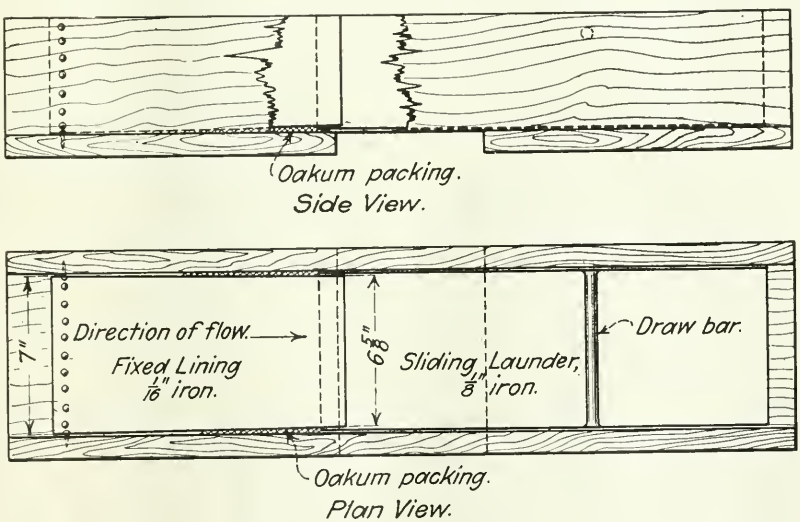
Classification and Fine Grinding

The Editor:

Sir—Under the above heading in your issue of October 16, Mr. A. E. Drucker seems to put the range limit for mechanical classifiers as –200 overflow product and a sand discharge.

In my own work I have had to call on the Dorr classifier to cover a much wider range, and have found it capable of easy adjustment to my needs. At the La Republica mine in old Mexico some eight years ago, a –100 overflow was required from a product made up of stamp-battery pulp (using a 20-mesh 0.023 wire) and tube-mill discharge. This was readily accomplished by using an adjustable baffle about 2 inches from, and parallel with, the back of the classifier. By raising or lowering this baffle, a wide range in overflow sizes can be obtained. In this case, I also used the front spray-pipe, and reduced the –200 product for the tube-mill to 1%.

By simple means I have always obtained classification very close to my needs below –100 overflow. A coarser overflow than this I have not needed to date, but know the division point can be readily and easily pushed up to coarser limits. Recently the same machine has been placed in extensive use for –48 and –60 overflows, returning oversize to the various ball-mills in common use.



In Mr. Drucker's absence abroad, this could easily have escaped his attention, as I recall no published accounts of this work.

Various plants can be cited using these machines, for example, the Anaconda Copper Mining Co. uses 52 simplex classifiers in closed circuit with Hardinge ball-mills, delivering a sandy product. The Inspiration Consolidated Copper Co. is using 18 large duplex classifiers, and is installing 18 more, delivering a −48 mesh product for treatment, and returning the oversize to large ball-mills. Many other mills have recently installed the same type of classifiers for delivery of coarse finished product.

The following is an actual screen-analysis of such work:

Mesh.	Screen size classifier sand.	Cumulative percentage classifier overflow.
On 28.....	32.2	0.0
On 48.....	71.2	0.64
On 65.....	84.9	5.89
On 100.....	91.5	14.89
On 150.....	94.4	....
On 200.....	95.7	....
Through 200.....	4.3	....

Colorado Springs, November 29.

Who Owns A Report?

The Editor:

Sir—Discussion on the question of who owns an engineer's report has naturally brought out differences of opinion. I should say that the one for whom he makes a report, and who has paid for it, has the first claim upon it. But it does not follow that the information is locked up in an engineer's brain forever, not to be used by him at any future time. If for the purpose of estimating the value of a mine, the buyer or the seller, as the case may be, has the prior right to that for which he has paid. But after the occasion for which the report is made has passed, and he knows that no further negotiations are in progress, the engineer may use the knowledge so gained for another client, with perfect propriety.

The knowledge which years of experience brings, makes up a large part of the engineer's capital. The particular information of any one district which may be the sum-total of perhaps a dozen mine-examinations, entitles his opinion to special credence. If then he does not bring to bear all his knowledge, previously acquired, in the case of his latest examinations, he is not giving full value to his last client; and he is in no sense defrauding his client who paid him the first fee, for the report which covers perhaps the general features of the district.

A specific report belongs to the party who pays for it, but as only in rare instances does a mine remain in an unchanged condition, the subsequent reports on the same mine, made at later dates, must be treated as distinctive, even though the fundamental facts learned at the time of the first examination, remain the same.

A professional man's sense of the proper use of knowledge, will always guide him in utilizing what he has learned, over a period of years and by reason of the opportunities which possibly conflicting interests have given him.

In many instances an engineer has been open to criticism for leaving the employ of one company and devoting his acquired knowledge to the neighboring mine. In case there has been no conflict of interest, harmful results are avoided, but it demands a very strict interpretation of the ethics of the situation to "keep off the rocks."

It is axiomatic that the chance to acquire adjacent property belongs first to the operating company by whom an engineer is employed and all territory that by any possible interpretation may be advantageous to his employer is not the proper subject of speculation by any employee of the company.

Reports may be verbal as well as written and the dissemination of information, except by specific consent of the client, should be carefully avoided, even though it be at the risk of exposing an engineer to criticism as uncommunicative.

F. L. Sizer.

San Francisco, November 15.

The Editor:

Sir—This question, asked in your issue of October 30, is, at the first thought, very easily answered: the client. And this, too, is good professional usage. But along with this question there are an infinite number of "dips and angles" that call for a qualifying answer.

The average client is inclined to play fair with the engineer, but there are some who do not. The ownership and control of a report (and the knowledge that made the report) should revert to the engineer in the following cases: when his buying client has turned down a property or has failed after a reasonable length of time to show active interest in it; and when his investigating client, of a district or region, for example, has had a reasonable length of time in which to make use of the report. Complicated conditions necessarily arise which are not subject to any single rule or standard which can be laid down.

Generally, I believe, an understanding between client and engineer before the examination is made would solve the question of ownership more satisfactorily than any set of rules or standards possibly could. The older established engineers can take liberties when, under similar conditions, the younger engineers could not, hence the latter more often suffer an injustice. Finally, let the engineer use his reports and knowledge in such a way that his client will suffer no financial loss, or injury of any kind.

Corey C. Brayton.

San Francisco, November 28.

Quarrying has a death-rate of 1.72 per 1000 employed, against 3.54 in metal and 3.73 in coal mines. Contrasted with underground work, quarrying is much less hazardous. The chief sources of accidents in quarries are haulage, falls of ground, and explosives.

Extra-Lateral Right

By L. F. S. HOLLAND

Introduction. Much of the litigation under the United States mining law originates in the provisions of Section 2322, Revised Statutes of the United States, 1872, which allows the right of extra-lateral pursuit in their descent into the earth, and in the direction of their dip, of all veins apexing within a properly located claim.

While the United States Supreme Court, the final arbiter upon all questions arising under the Federal laws, has by no means established a precedent for the interpretation of the law in all conditions affecting extra-lateral right, certain principles have been fairly well established in various courts, and a digest of such decisions is here presented in the hope of affording some assistance to the locator and miner in protecting his rights.

Acknowledgements are made to Dr. Rossiter W. Raymond's contributions to the Transactions of the American Institute of Mining Engineers, volumes XII, XV, and XVII; 'Lindley on Mines,' 3rd edition; Costigan on 'Mining Law'; Shamel, 'Mining, Mineral and Geological Law'; Morrison and De Soto, 'Mining Rights,' 13th and 14th editions; and United States Bureau of Mines, 'Abstract of Current Decisions on Mines and Mining.' As these publications are commonly accessible to mining men, and are found in most public libraries, references are made to them here where possible, as well as to the usual law reports, which generally are found only in law libraries.

Preliminary Requirement. To allow of extra-lateral pursuit under the act of 1872 the vein or lode (1) must be "in place"; (2) it must have an apex; (3) it must be continuous and its identity must be preserved as a geological fact, though the fissure may be interrupted or nearly closed. In a properly located claim (a) the end-lines must be parallel, or at least not diverge in the direction of the dip of the discovery vein,[1] (b) the end-lines must be continuous and unbroken.[2] However, extra-lateral right attaches to irregularly-shaped locations that were made prior to the act of 1872.[3]

The Ideal Location. The highest type of a perfected location is described by Lindley as "a rectangular parallelogram, the lines crossing the apex of the lode at right angles to the general course of the vein, termed in law the end-lines, the extremities of which are equi-distant from the centre of the vein, the side-lines parallel to the course of the vein; that is, equi-distant throughout from a line drawn through the centre of the apex on its longitudinal course."[4] Under Section 2322 the extra-lateral right flowing from such a location is unquestioned, but unfortunately for the application of the law such conditions are rarely even approximated.

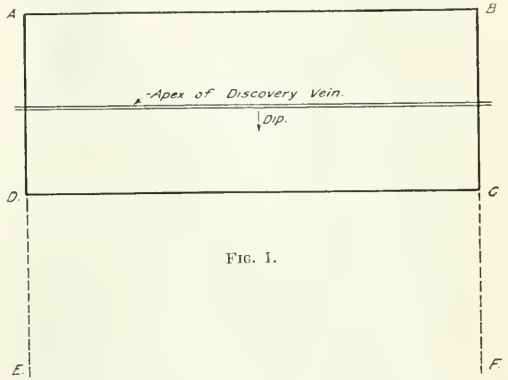

Fig. 1.

Fig. 1 represents the ideal location. The vein may be followed extra-laterally within vertical planes through the end-lined *AD*, *BC*, prolonged to any distance desired in the direction *E* and *F*.

Exception. A vein that is horizontal or does not descend from the horizon is a "blanket vein," and has no extra-lateral right, for the reason that the whole upper surface is really its apex strike, and to allow extra-lateral right would be to allow it on the strike of the vein. If, however, a vein descends from the plane of the horizon, though the angle be very slight, it departs "from a perpendicular" within the meaning of Section 2322.[5]

Anticlinal Vein. In a decision handed down in the Jim Butler *v.* West End case, by Judge Averill of Tonopah, Nevada, as recently as April 30, 1915, it was held that extra-lateral right extends downward from an anticlinal axis or common apex of a vein in a given claim beyond both side-lines of the claim. The case was discussed by H. V. Winchell in the Mining and Scientific Press of May 15, 1915.

Int., 689. Jack Pot Lode Mining Claim, 34 L. D., 470. Belligerent and other lodes, 35 L. D., 22; Lindley Sec. 583; Costigan, p. 414; Shamel, 233-236; Morrison, 170.

In Fig. 2, which is reproduced from Mr. Winchell's article, the arrows indicate the dip of the vein on either side of the anticlinal axis. The owner of the claim was held to have extra-lateral right in both direction. Judge Averill's decision may, or may not, be upheld in the higher courts.

Broad Vein on Both Sides of a Common Side-Line. The senior claim takes the entire width of the vein on its

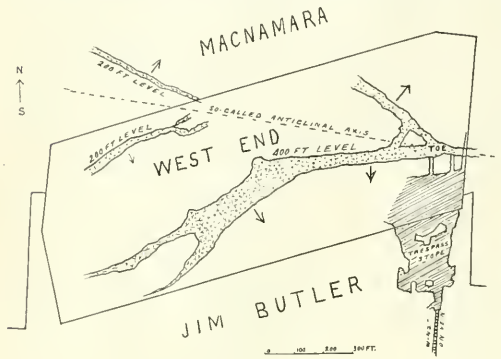

Fig. 2.

dip if the claim is in other respects so located as to give it extra-lateral right.

In Fig. 3 the Viola claim, being the senior location, takes all the ore between the extended end-lines *ADE*, *BCF*. The San Carlos gets no ore between these lines,

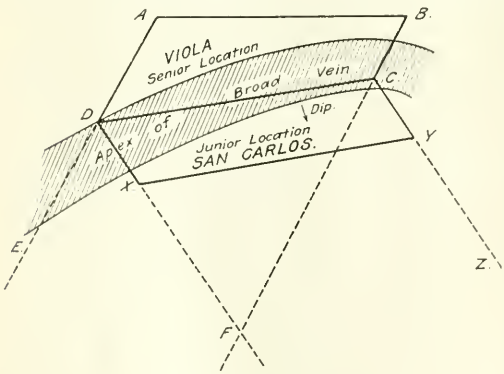

Fig. 3.

but is entitled to the ore between *FC*, *CZ*, which is outside of the limits of the senior location's extra-lateral right.[6]

Discovery-Vein Entering and Departing Through the Same Side-Line. The Supreme Court of Colorado has held that the Fulton claim, represented in Fig. 4, whose discovery-vein twice crossed one side-line, but did not cross either end-line, had no extra-lateral right. Some authorities doubt if this decision will be upheld should the question have to be considered by the United States Supreme Court. It may here be noted that a side-line need not be a straight line.[7]

Discovery-Vein Crossing Two Parallel Side-Lines. The extra-lateral right is in the direction of the dip of the vein and is determined by producing indefinitely the located side-lines in that direction. The located side-lines are treated as the legal end-lines and the located end-lines are treated as the legal side-lines. The angle at

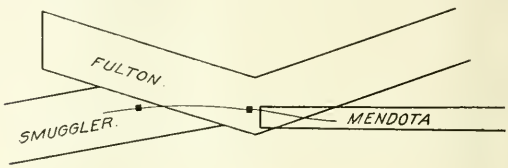

Fig. 4.

which the discovery vein crosses the located side-line is of no consequence to the extra-lateral right.

In Fig. 5 the Amy claim had no extra-lateral right on the north side of the located side-line *AB*, which became a statutory end-line, but the vein could be followed on its dip within the limits of the lines *ABE* and *DCF* produced indefinitely.[8]

Discovery-Vein Crossing Two Opposite Non-Parallel Side-Lines. While there is no requirement of the law that side-lines should be parallel, and there are no decisions to follow as precedents, it is probable that in

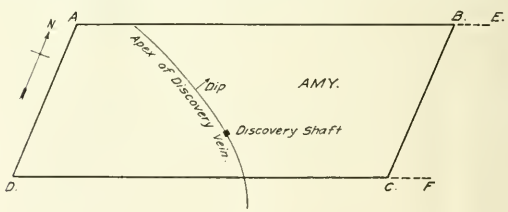

Fig. 5.

the case of non-parallelism of side-lines, the claim would be held to have no extra-lateral right if its side-lines diverge in the direction of the dip of the discovery-vein, but if they converge, the vein may be pursued in its downward course to the line of intersection of the two planes.[9]

Discovery-Vein Crossing One End-Line and a Side-Line. The law is now well settled that the extra-lateral right in this case is to the segment of the vein, through-

out its entire depth, bounded by a vertical plane through the crossed end-line produced indefinitely in the direction of the dip, and a parallel plane through the point where the vein crosses the side-line.

In Fig. 6 the extra-lateral right of the New York claim is between the vertical plane *BCE* produced in-

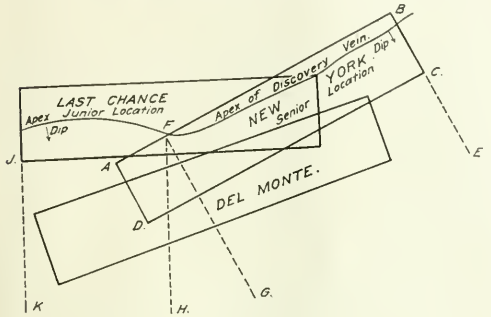

Fig. 6.

definitely in the direction of the dip of the discovery-vein, and the parallel plane *FG* through the point *F*, where the vein crosses the side-line *AB*.[10]

Discovery-Vein Crossing Three Boundary Lines of Claim. There is no right to any part of the vein, the apex of which part is outside of the claim.

In Fig. 7 the locator would have extra-lateral right

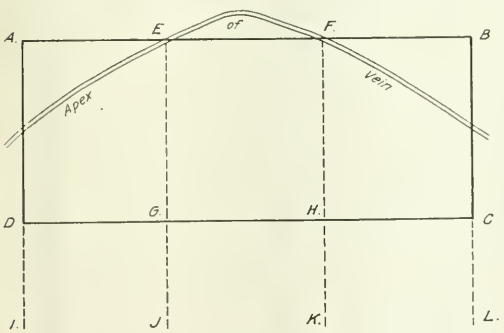

Fig. 7.

between the planes *ADI* and *EGJ*, and between the planes *BCL* and *FHK*, but not between *EGJ* and *FHK*.[11]

Discovery-Vein with Apex Wholly Within the Claim, Reaching No Boundary Line or Only One Boundary Line. While there appears to be no adjudicated case, the dicta in the Del Monte and Carson City cases affirm that extra-lateral right is preserved and is defined by planes through the terminations of the vein drawn parallel with the located or statutory end-lines, according to the parallelism of the vein.

Fig. 8 and 9 represent two of several situations falling within these conditions.[12]

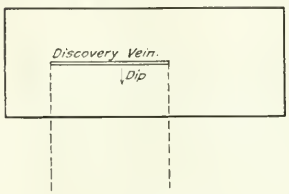

Fig. 8.

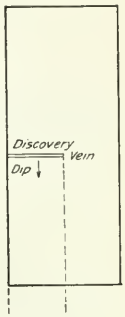

Fig. 9.

Secondary or Incidental Veins. The extra-lateral right as to all veins apexing in a claim is governed by the extra-lateral right of the discovery-vein and is defined by the same set of end-line planes as limit that right on the discovery-vein. Such planes are applied at the extremities of the secondary veins, parallel to the end-lines of the claim. If the discovery-vein has no extra-lateral right, the secondary veins have none. Furthermore, if the planes defining the extra-lateral right of the discovery-vein are parallel or coincident with the course of a secondary vein, there is no extra-lateral right on the secondary vein.[13]

Morrison states (13th edition, page 178; 14th ed., 203) that the decision in Ajax *v.* Hilkey (31 Colo., 131; 102 Am. St. Rep., 23; 72 Pac., 447; 22 Morrison Min. Rep., 585; 62 L. R. A., 555) is inconsistent with the other rulings cited, whereas Lindley says (Section 594, page 1394), "We think the decision in Ajax Mining Co. *v.* Hilkey states the correct rule." Costigan (page 443) agrees with Lindley.

In Fig. 10, representing the Victor Consolidated claim in the Ajax *v.* Hilkey case, the secondary vein had extra-lateral right between *EF* and *GH*, although the extra-lateral right of the discovery-vein was only between *AB* and *CD*. The ruling of the Court was that "Such rights

as to secondary veins are not confined to such veins as apex within the same segment of the claim in which the apex of the discovery-vein exists; and while the end-lines of the location, as fixed and described in the patent,

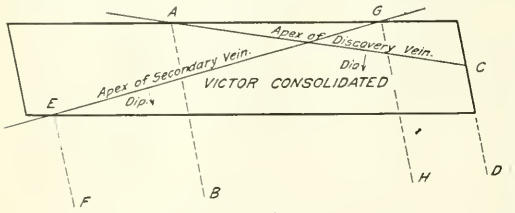

Fig 10.

are the end-lines of all veins apexing within the surface boundaries, and may constitute the bounding planes for such extra-lateral rights, and in no case can the locator pursue the vein on its dip outside the surface lines beyond such planes continued in their own direction until they intersect such veins, yet these bounding planes, which in all cases must be parallel to the end-lines, need not be coincident."[14]

Conflicting Surface Locations with End-Lines at Different Angles. After satisfying the extra-lateral right of the senior location, the junior location has the 'judicial apex' and is entitled to the part of the dip unlocated by the senior claim, within the segment bounded by the extended end-line planes of the junior claim. Lindley says (Section 594), "Construct extra-lateral right planes on the junior claim as if there were no conflict. Subtract the segment of the vein to which the senior is entitled. The remainder belongs to the junior claim." In Fig. 6 the New York claim's extra-lateral right is between the vertical planes *B C E* and *F G*. The extra-lateral right of the Last Chance claim is between *FG* and *JK*, which includes the segment *HFG* as well as *JK, FH*.[15]

Vein Dipping Under Senior Agricultural Grant. In the only reported case it was held that a vein cannot be followed on its dip through a prior agricultural grant.[16]

Practically all Latin-American and European countries employ the metric system of weights and measures. This makes difficulties and misunderstandings when business is conducted with firms in the United States and England where the English system is used.

Determination of Tungsten

These notes from 'Analysis, Detection, and Commercial Value of the Rare Metals,' by J. Ohly, are timely.

Detection. The presence of tungsten is readily ascertained by boiling the finely powdered mineral with a mixture of four parts of hydrochloric acid and one part nitric acid for about two hours in a porcelain dish, when, in case the ore contains tungsten, yellow spots of tungsten trioxide will be discernible. The trioxide is insoluble in dilute hydrochloric acid. If heated in the oxidizing flame of the blow-pipe with borax or phosphorous salt, all tungsten compounds form colorless beads. In the reducing flame they produce with borax a yellow glass, in case the quantity of tungsten is large. Small amounts added to the bead leave it colorless. When heated with a phosphorous salt in the reducing-flame a glass of pure blue color is produced, as long as tungsten compounds are present exclusively. On adding a particle of iron salt to the bead it assumes a blood-red coloration, and on introducing tin the bead becomes blue or bluish-green.

Chemical Reactions. The trioxide is almost insoluble in a large excess of hydrochloric or nitric acids, which circumstance distinguishes it from molybdenum trioxide, MoO_3; but it dissolves readily in ammonia. Sulphuretted hydrogen, H_2S, produces no precipitate in acid solutions of tungstates, but reduces the WO_3 to the blue oxide W_2O_5. Ammonium sulphide, $(NH_4)_2S$, produces no precipitate from alkaline tungstates, but on acidulating with hydrochloric acid light-brown tungsten trisulphide, WS_3, is precipitated, slightly soluble in pure water, but insoluble in the presence of salts. The solution is colored blue. The precipitated sulphide dissolves readily in ammonium sulphide. Tin chloride, $SnCl_2$, gives at first a yellow precipitate; on acidulating with hydrochloric acid and applying heat the precipitate acquires a beautiful blue color. Zinc sub-sulphite reduces tungsten compounds to a deep brown tungstous oxide of unknown composition; in small quantities a deep blue color only may be produced.

Quantitative Determination. Reduce the ore to a very fine powder, weigh one gram and digest for 12 hours (over night) at a gentle heat with a mixture of four parts hydrochloric and one part nitric acid, till yellow pulverulent tungstic acid remains. Evaporate to dryness on water-bath, and take up with water acidulated by hydrochloric acid. Filter, wash the residue, consisting, besides the yellow trioxide, of silica and sometimes small quantities of niobic acid, with alcohol, and treat the mixture on the filter with ammonia. Place the filtrate in a large weighed porcelain crucible, evaporate to dryness on the water-bath, and heat the residue of ammonium tungstate to decomposition. Weigh the crucible with the remaining trioxide and calculate the percentage.

In a separate part of two grams of the ore, placed on a large watch-glass, determine the water-content by heating in an air-bath to 110° C. for a couple of hours. Moisture is shown by loss in weight.

A Fluorspar Mine in Colorado

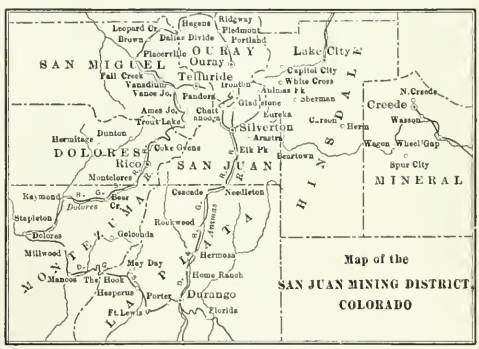
By HORACE F. LUNT*

Wagon-Wheel Gap, in Mineral county, Colorado, where the Rio Grande has cut a narrow pass through a ridge of hard rhyolite, was, apparently, one of the first localities to be named by the white settlers of the region, as it appears on the earliest maps. Perhaps it was named by General Frémont, 'the Pathfinder,' who is supposed to have wintered, during one of his exploring expeditions, in a fortified camp the ruins of which can be seen today on the cliffs that form the south side of the Gap. The hot springs on Goose creek, a mile south of the Gap, are equally well known and the Indians are said to have made use of their curative properties since time immemorial. Previous to the discovery of the rich mines of Creede in 1891, what is now known as the Creede branch of the Denver & Rio Grande railroad ended at Wagon-Wheel Gap, eight and a half miles south-east of Creede.

The fluorspar vein is just across Goose creek, to the east, from the hotel and bath-house at the hot springs. It was located many years ago for its supposed value as a precious-metal deposit, the locators believing that they had discovered an extension of the Amethyst vein, from which has come most of the ore that the Creede district has produced. As with many another prospector's hypotheses, there are no real facts to support this idea, but it is easy to see how it originated. Both veins strike in the north-west quadrant, the country-rock is the same, and the radiating crystals of purple fluorite in many specimens bear a surprising superficial resemblance to the amethystine quartz of the Creede mines. Many assays of the vein-matter and wall-rock gave returns of from $2 to $7 per ton in gold and silver.

In 1911 the prospect was visited by S. B. Collins, a mining engineer of Creede, who at once recognized the true character of the vein-filling. Subsequently he purchased the property and in 1912 and 1913 developed it, extracting about 5000 tons of fluorspar, which was sold to the Colorado Fuel & Iron Co. for use as flux in its open-hearth steel furnaces at Pueblo. Owing to the curtailment of steel-making operations, the demand for fluorspar ceased and the mine was shut-down in February, 1914. Recently a new contract has been made with the Colorado Fuel & Iron Co. and the mine is being cleaned out preparatory to resuming shipments. In a short time Mr. Collins expects to be producing 600 or 700 tons per month. The mine is so far from other markets that it is entirely dependent on the Colorado Fuel & Iron Co. as a consumer of its product.

The rocks in the vicinity are all intrusive, of Miocene age, and have been correlated with the Potosi series of the San Juan country[1]. The most prominent is a reddish fluidal rhyolite. Rhyolite tuffs and breccias, latite, and andesite have also been identified. The vein in which the fluorite occurs is a fissure, or fissured zone, in the rhyolite tuffs and breccias, and possibly in some places in the solid rhyolite flows. The wall-rock is so highly altered that in many places its real nature cannot be determined. It contains pyrite, sometimes in considerable quantity, generally altered to limonite or hematite. The vein-filling consists of fluorite, barite, altered country-rock, and gouge. Very little barite has been found more than 200 ft. from the surface, thus giving



the impression that it may disappear entirely as depth is gained. A few large cavities have been found filled with what appears to be pure kaolin containing minute crystals of fluorite. A little calcite is seen occasionally. The fluorite is white and massive with a sugary appearance, or in translucent, colorless to deep purple, crystalline crusts. The characteristic cubic crystals are not well developed and the exact crystal form is not usually apparent. Open cavities are common and are frequently lined with barite crystals on the fluorite. Nearly all the fluorite shows ribbon structure, or banding. Occasionally it has a greenish tinge instead of the prevailing purple.

The vein outcrops on the steep hillside forming the east bank of Goose creek and has been traced to the top of the hill, 700 ft. above the creek-bed, and for about half a mile farther east. No trace of it has been found west of the valley. The strike varies from north, 80° east to nearly due east and west. The dip is from 70° to 80° south. The most important workings are two adits. The lower one is about 75 ft. above the level of the creek. For the first 100 ft. it follows a sheeted zone,

*Mining engineer, Colorado Springs, Colorado.

[1]W. H. Emmons and E. S. Larsen, 'The Hot Springs and Mineral Deposits of Wagon-Wheel Gap, Colorado.' *Economic Geology*, Vol. 8, pp. 235-246.

two or three feet wide, which contains small stringers, seldom more than a couple of inches wide, of barite and fluorite. From the 100-ft. point the fluorite stringers become larger and in places the vein is six or eight feet wide with three or four feet of solid fluorite. The adit is 600 ft. long with a good showing at the face. The upper adit is about 500 ft. above and 1200 ft. farther east than the lower. The first 40 ft. is a cross-cut, beyond which it follows the vein for 200 ft. The character of the vein here is the same as in the eastern part of the lower adit. Above the upper adit are several surface tunnels and open-cuts from which most of the fluorspar produced was extracted. There is practically no spar left in any of them, excepting in the bottoms.

The flourspar and contiguous rocks are soft and are mined without difficulty by hand-drilling. The altered wall-rock is inclined to slough off in some places, but is easily held by light timbers. The large fluorspar streaks are generally divided from the wall-rock and the horses of country-rock in the vein by gouge, so that the shipping product is readily kept free from extraneous matter without elaborate sorting. The spar from the upper adit is dumped from the mine-cars into a small bin at the upper terminal of a jig-back aerial tramway, 1600 ft. long, which conveys it to a storage-bin of 400 tons capacity near the lower adit. The mine-cars from the latter are dumped directly into the bin. From this bin the spar is hauled to the railroad at Wagon-Wheel Gap by wagon or sled.

The run-of-mine fluorspar from this deposit is unusually pure. An analysis of the various shipments made to the Colorado Fuel & Iron Co. shows the following principal constituents: calcium fluoride, 90.08%; calcium carbonate, 1.17; oxides, chiefly sesquioxide of iron and alumina, 2.14; barium sulphate, between 3.22 and 6.00%[2]. It would undoubtedly be possible, by careful sorting, to ship a product that would run over 99% calcium fluoride if there were any object in so doing.

Two of the three hot springs previously mentioned are on a direct line with the vein. Presumably the spring-water comes from the vein. This water is described as "alkaline-saline, sodic-calcic-magnesic, sulphated-muriated-lithiated." No mention is made of fluorine in the analyses in the pamphlet issued by the company that owns the springs. An analysis of the travertine surrounding one of the springs shows 0.22% fluorine, corresponding to 0.45% fluorite. There seems to be no reason to doubt that the spring-water is of deep origin and from the same source as the waters that deposited the fluorite of the mine[3].

ARGENTINA has an area of 1,153,418 square miles, and a population of 9,000,000, of which Buenos Aires, the capital, has 1,700,000. Exports of coal from the United States to Argentina for the eight months ending March 1, 1915, were 184,393 tons as against 76,410 tons in the corresponding period of the year before.

[2]'Mineral Resources of the United States' for 1913, Part 2, p. 377.

Mining in Colorado

By GEORGE J. BANCROFT

The most important development in mining matters in Colorado within the past few weeks is without doubt the sharp advance in the price of silver. The stimulating effect of this advance is partly sentimental. The increase in the price of zinc means as much in dollars and cents based on present output as does the improvement in the price of silver. But high silver to the mining industry of this State is like plenty of oats to a spirited horse. It makes business prance with energy. Luckily or unluckily, according to the viewpoint, the present rise in the price of silver is not taken very seriously as yet by our experienced mining public. The fundamental causes of the advance are too little understood to inspire confidence of continuation. There is a feeling that the rise is an evanescent consequence of the War. There is, however, this hopeful feature: the silver-using nations are largely producers of foodstuffs and hence are waxing prosperous on war-orders, thereby becoming able to buy and coin more silver. To what extent this condition may prove an important and lasting factor in upholding the price of the metal remains to be seen. At present our mining men are hopeful, but cautious, and the customary enthusiasm attendant upon an improved market for silver is held in leash.

Flotation methods have been adopted with avidity throughout Colorado. There are now 24 flotation plants of one kind or another in the State. Most of them are small additions to existing mills and are little more than experimental plants. Such a large number of these installations have been successful that there is no doubt of the utility of the process to our mines. Colorado is primarily a state of many small concentrating plants. There are relatively few large installations and relatively little ore that is entirely free-milling, cyaniding, or straight-smelting in character. Most of it is concentrated on the ground. Even in the Cripple Creek cyanide mills it is customary to do more or less concentration. Furthermore the oxidized zone has long since been passed in most cases. To one who understands the process, its applications and limitations, it can readily be seen that it will be a very important factor in Colorado ore-dressing.

A rather unexpected application is reported from Cripple Creek, where it is said that the big Portland cyanide mill will be remodeled for a flotation plant. The Portland dump is now being sent through the old Stratton's-Independence mill and it is planned to send all oxidized or partly oxidized ores to this cyanide mill, keeping the flotation plant for the purely sulphide ore, which by the very nature of things, is difficult to treat by cyanide and easy to treat by flotation. Not many Cripple Creek mines can afford two mills, and for a general all-round process, it is doubtful if cyanide will soon be replaced at Cripple Creek. It is probable, however, that small flotation auxiliaries will be found useful.

Electro-Static Separation of Pyritic Zinc Ores

By J. H. LEWIS*

The history of the zinc-mining region of the upper Mississippi River valley is well known. Not until well into the sixties was much attention given to the mining of zinc ore. After the Civil War two young Bavarians, Matthiesen and Hegeler, came to Wisconsin in quest of zinc ore; their experience in Germany aided them largely, and resulted in the first zinc smelter in the United States being established at La Salle, Illinois. As soon as this market became available the miners turned their attention from the early lead deposits to the mining of zinc ore, both carbonate and sphalerite, of which the region offers large deposits. Crude methods prevailed, and practically the core of the orebodies was mined by hammer and steel. Not until 1904 was there a general awakening to the possibilities of modern mining equipment driven by steam, gasoline, or electric power. Just what rapid strides were achieved may be guessed, when it is said that the output in 1904 averaged about 2000 tons of crude concentrate per month, whereas at the present time the production has been increased to nearly 5000 tons per week.

In the early stages of local practice, using ordinary methods of wet concentration, the problem arose of securing a clean product for the market. It was found that the average concentrate contained only 30% zinc. The amount of high-grade ore sorted from the run-of-mine was small, and with the prices ordinarily prevailing prior to August 1914, it was found that unless this low-grade concentrate could be quickly and cheaply converted into a high-grade commercial product, very little profit would result. This led to serious investigation.

The pioneers in this work were A. N. Swart of Denver, now with the Guggenheims, and an associate named Pflumm. They experimented at the old Empress mine in the Benton district during 1896. Their plant was as intricate as it was crude. Although they failed at that time to accomplish anything, the knowledge gained finally led to the first really successful electro-static separation plant. Prior to this, Frank Trego, a brilliant young man, tried a machine in which the first step was to roast off the sulphur atom found intimately associated with most Wisconsin sphalerite. The ore was fed to a revolving base, built into a fire-brick cupola, the flames playing on the traveling ore from a chimney, the draft deflecting the flame downward. The roasted ore was then passed under highly magnetized poles, but the best that Trego could do was to secure a concentrate containing about 9% iron.

At the time that he was struggling with this complex problem, Charles C. Mathey, then as now, president of the Galena Iron Works Co., at Galena, Illinois, designed a revolving cylindrical hearth built of boiler-iron, and lined with fire-brick, in which annularly formed grooves extended around the drum. One end was open, and built into a furnace, while the other, slightly inclined, received the raw concentrate. The flames played on the ore as it followed its course through the hearth, the temperature being held at about 450°F., or just below the melting point. The red-hot ore fell into a tube in which propellers operated, and the ore was wormed out, being gradually distributed on a conveyor-belt passing under highly magnetized poles. The Mathey was the first of this type of machine to be a success, but in the process, the sulphur atom was entirely lost, and this was of value in the manufacture of commercial sulphuric acid. After years of absence, A. N. Swart again appeared on the scene. Instead of volatilizing the sulphur atom, the ore was first dried thoroughly in kilns. It was then conveyed to the top of an elevator-shaft, after being crushed to the proper size and then dropped onto screens, the elevator acting as an escape for the hot air from the dryers. From the screens the ore was distributed to the electro-static machines, where high-grade zinc product was made, and the pyrite conserved.

Two types of machines had been introduced, the Blake-Morscher of Denver, and the Huff No. 1 and 2 of Boston. The latter gave better results on the Wisconsin ore, and finally held the field against others. This plant, built mainly as an experimental station, cost $50,000, and was destroyed by fire after operating successfully and profitably for three years.

The period following the destruction of this plant was characterized by a steady demand for low-grade concentrate at a price that appealed to the miners of this region, because it gave a fair profit, but many extremely low-grade producers closed entirely, and scores of abandoned plants could be seen all over the district. Dry separation was again studied during the current year, when miners found no market for a low-grade product, that is, concentrate under 57% zinc. It was this situation that forced producers to resurrect some of the old separating plants, and in most cases to build new ones. By the end of 1915 there will be 12 plants of this type at work in the Wisconsin region, with a total capacity of 5000 tons of crude concentrate per week.

Up to the present time five distinct types of magnetic separators have been devised, and it is interesting to note the principal features of each:

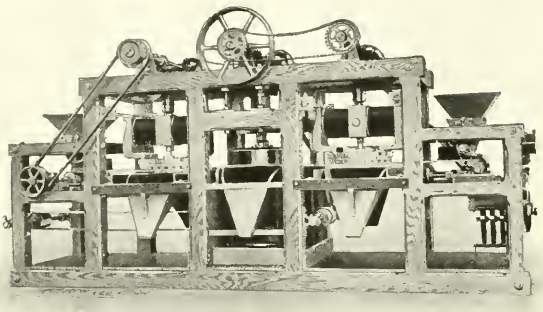
1. The revolving cylinder or drum, in two classes, (*a*) with magnetic fields created in grooves extending around the drum, and (*b*) with fields lying over or between pole-

*Platteville (Wisconsin) correspondent of the MINING AND SCIENTIFIC PRESS.

pieces extending around the face of the drum. These machines are for coarse material.

2. The double-pole crossed or tangent-belt machine, including a variety of belt-machines. This type consumes a great deal of energy; it requires close attention and frequent adjustment.

3. In which the magnetic particles are deflected out of the course of a falling stream of material. Machines of this type have the advantage of large capacity, and of producing a fairly clean magnetic material.



GENERAL VIEW OF SEPARATOR.

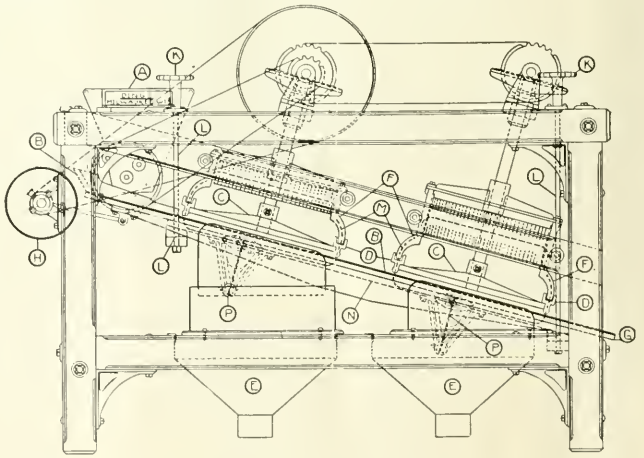
4. Vertical, single, or multiple magnets, revolving partly over a belt carrying the material to be separated. These machines produce fairly clean magnetic products when not crowded.

5. In which magnets oscillate from side to side directly across a flowing stream of material. Such is the Waring separator, installed at the Mills mine in the Hazel Green field, but was not efficient considering the quantity of material treated.

The ideal magnetic separator, to produce at a single operation perfectly clean, non-magnetic material, and equally clean magnetic products, assuring a large capacity with a minimum consumption of energy, requiring little attention or repair, and perfectly free from such defects as heating coils, burning out, etc., has yet to be invented.

All the requirements of the ideal machine are met, however, by combining the best forms of type No. 1, class (*a*) and type No. 4.

The New Jersey Zinc Co., at its separating-plant, operated in connection with the sulphuric-acid department at Mineral Point, now being rehabilitated after a shut-down of four years, on account of suits against the company for damage to shrubbery and lawns by fume, has five of the Mathey type of drum and Dings electro-static separating machines. Two types of this machine are now employed in combination at the Wisconsin Zinc Co. roasters at Platteville. At the National separating works in the Cuba district, the same methods prevail, but a different course is followed in preparing the ore. Instead of roasting the ore, it is crushed fine, thoroughly dried, and then distributed for separating into the different machines. Here, and at the Campbell separating plant, also owned by the Wisconsin Zinc Co., the pyrite is saved and sold, realizing about $3.75 to $4 per ton, an item not to be disregarded, as will be seen later. The Campbell type of plant is also working in the Linden district, but its capacity is limited. Another plant is being erected for the Wisconsin Zinc Co. at New Diggings, under the supervision of Homer S. Snow, general manager for this corporation. It will have a greater capacity than any plant in this region, being able to treat 150 tons of crude concentrate per 24 hours. This plant will house 10 of the Dings and Cleveland-Knowles machines, no expert labor being required. The National Zinc Works plant at Cuba is capable of handling 800 tons of crude concentrate per week. At this, as well as at the plants operated for the Wisconsin Zinc Co., the supply of ore comes from mines affiliated with the parent company, so that no outlet is offered through them to the small independent operators, many of whom cannot well afford the cost of building a complete separating-plant. This difficulty is being overcome gradually by custom roasters and separators operating at other points.



DINGS ELECTRO-STATIC SEPARATOR.

A—Hopper. B—Vibrating conveyor. CC—Wheels carrying secondary magnets. DD—Secondary magnets. EE—Discharge spouts. FF—Pole pieces of primary magnets. G—Discharge end of conveyor. H—Driving pulley. KK—Hand wheels, for adjusting inclination of conveyor. LL—Hanger rods. M—Magnetic circuit. N—Steel bridge. PP—Conveyor supports.

An example of magnetic separation is as follows. The average concentrate handled at the National Zinc Works, Cuba, shows the following composition:

	Raw product, %		Concentrate after separation, %
Water	2.80	Zinc	60.45
Zinc	34.40	Iron	2.38
Iron	17.00	Sulphur	30.00
Lime	1.90	Lime	1.84
Lead	0.30	Lead	0.30

The iron concentrate after separating contains about 4% zinc and 30% sulphur. The Wisconsin Zinc roasters at Platteville show a raw concentrate somewhat lower in both zinc and iron, with a finished product almost as high in value as that shown for the product obtained by aid of the process employed in the Cuba plants.

There is no uniformity in the concentrate produced locally. In fact, the metal-content ranges from a high-grade wet concentrate assaying 60% zinc to a concentrate as low as 20% zinc, and even leaner. In the very low grades, the expense of reduction is higher, but as the ore is worthless in its native state, it becomes obvious that it pays even to handle such low-grade ores. This statement is sustained by a report issued by Luther V. Rice, of the Fields Mining & Milling Co. (R. W. Hunt & Co., Chicago), general manager of the famous Crawhall and Thompson mines in the Shullsburg district. Here, 154 tons of 20% product was treated, from which 52 tons of 54% zinc concentrate was recovered. In the first instance the ore was unsaleable. Under the terms of a contract binding the Fields M. & M. Co. and the New Jersey Zinc Co., the finished product brought $111.11 per ton, although at the date of sale blende was freely quoted at $75 per ton. The cost of roasting and separating, including fuel and labor, according to Mr. Rice, was $300 for the 52 tons. In this case he had to consider the benefits accruing under a contract wherein sales are controlled by the ruling price of spelter. In all general transactions, open-market offerings governing the sale of ore, the profit is, of course, the great incentive to producing a high-grade concentrate. The relative loss in the concentrate treated is more than offset by the gain in profit on the finished product. It is unreasonable to think, or expect, that smelter representatives will enter into an agreement with ore-producers whereby they will be paid more relatively for a low-grade ore than for a high-grade separator product. Some instances exist, but when these contracts expire, as most of them soon will, sales will come in more generally on open-market offerings, and the advantage of the separating-plant will become increasingly apparent.

A retrospect of the field, now producing about 5000 tons of crude concentrate per week, impresses one with the great progress possible in metallurgy. The scope of operations is being enlarged daily, some of the most active producers having been developed from virgin soil within the past six months. That further progress will also be made in the reduction of low-grade zinc concentrate is certain, as engineers and metallurgists are diligently laboring to perfect a machine that will treat the raw product at one operation instead of the present combination processes, the consequent simplification and need of such an improvement being readily apparent.

Dredging at Panama

The Canal is closed indefinitely, and interest centres on the removal of the material forming the slides. Excavation from Gaillard cut during October amounted to 1,079,663 cu. yd., according to the *Canal Record*, compared with 1,052,586 yd. in September, 991,879 yd. in August, and 692,109 yd. in July. In October 872,952 yd. was taken from the bases of the Culebra slides.

Excavation in the seven days ending at 6 a.m., November 2, amounted to 257,029 yd., of which 236,549 yd. was from the Culebra slides. In addition, 8700 yd. was re-handled.

Excavation from the bases of the Culebra slides during the week ending at 6 a.m., October 26, amounted to 212,699 yd. Other excavation from the cut amounted to 61,246 yd., making a total for the week of 273,945 yd. The work by the several dredges during the two weeks was as follows:

Dredge and type.	Yardage. Oct. 26.	Nov. 2.
Gamboa, 15-yd. dipper	72,265	58,225
Paraiso, 15-yd. dipper	56,035	66,910
Cascadas, 15-yd. dipper	.....	5,640
Corozal, ladder	32,783	44,655
Cardenas, 5-yd. dipper	Repairs	Repairs
Chagres, 5-yd. dipper	25,610	9,320
Mindi, 5-yd. dipper	18,691	17,161
No. 86, pipe-line suction	34,080	29,180
Culebra, sea-going suction	27,166	26,912
Marmot, Belgian ladder	7,315	7,720

The 15-yard dipper dredge *Paraiso* broke a spud on October 25 and was towed to the north end of the cut for repairs, the spud being handled by the crane *Ajax*. The *Cardenas* was out of service during both the weeks for repairs, which were made at Paraiso. The ladder-dredge *Marmot* was taken out of the cut two days of the week ending October 26 to dredge away spoil which had obstructed a culvert under the Panama railroad north of Gamboa.

Salvador, the smallest of the Latin-American republics, is by no means the least populous. With an area of but 7325 square miles, which is less than that of New Jersey, it has a population of 1,700,000, which is equal to that of Kansas, while San Salvador, the capital, has 75,000. It is the only Central American republic that does not front on two oceans; its coast-line being on the Pacific. The total length of railways is but a hundred miles; however, a railroad is under construction that will connect with the railway system of Guatemala and will give Salvador a direct outlet to the Atlantic. Although in the tropics, Salvador has an equable climate by reason of the mountainous nature of the country. The annual production of gold and silver is between $1,000,000 and $1,500,000. The United States imports from and exports to Salvador to an extent greater than any other country. Salvador appears to lack currency, its supply aggregating only $11 per capita, including both circulating coin and credit money; nearly 30% of the governmental revenues appears to be required to meet foreign loans.

Vanadium

*Twenty years ago deposits of ores of vanadium were so little known and the use of the metal so ill-understood that its price per pound was in the thousands of dollars. Today at Pittsburg ferro-vanadium is quoted at $2.25 to $2.50 per pound of contained vanadium. The discovery of vanadium ore in Peru, and a better realization of the desirable qualities of the metal as an alloy in the making of high-grade steel, have united to increase its production to more nearly a commercial basis. The output in the United States of steel containing vanadium increased from less than 1000 tons in 1905 to nearly 100,000 tons in 1912, and, it is estimated, will reach 400,000 tons for 1915.

It is thought that the name vanadium was derived from Scandinavian mythology: the Swedish chemist, Sefstrom, named the element about 1830 during investigation of Swedish iron ores from which a remarkably soft and ductile iron had been produced. Vanadium compounds were first utilized for the manufacture of aniline black and indelible ink. Practically the first record of its use in steel was in 1896, when three armor-plates were made at the Firming steel works in France; these plates were notably superior to ordinary steel, but at that time no adequate supply of vanadium existed. In 1900, Prof. Arnold of Sheffield, England, made a series of tests that indicated that the addition of vanadium to steel raised the elastic limit 40 to 100% and increased the tensile strength 10 to 60% without affecting the ductility of the steel; chrome-steel containing vanadium likewise showed remarkable strength.

The real commercial value of vanadium was not realized until 1905 when M. Antenor Riza Patron, an engineer prospecting in the Peruvian Andes, discovered an important deposit of vanadium ore. The principal mines are operated now by the American Vanadium Co. of Pittsburg; Señor Patron is connected with the company in a consulting capacity, while Señor Fernandini, on whose property are the richest of the mines, is vice-president of the mining company.

Mining is by open-cuts and tunnels; native Indians acclimated to the rare atmosphere of 16,000-ft. altitude do the manual labor. The ore is roasted at the mines to reduce the sulphur and to concentrate the material to be shipped. The mines, at Mina Ragra, are 32 miles from the famous copper mining settlement of Cerro de Pasco. Llamas are employed to carry the concentrate in sacks of 125 lb. each over the steep and rocky mountain-paths six miles to lake Pun Ruyn where boats take it to the Peru Central railroad at a point 28 miles from the mines. These interesting animals, llamas, work under all conditions of weather, but positively will refuse to move if the bag of ore is an extra pound or two too heavy. At the plant of the American Vanadium Co. at Bridgeville, Pa., the concentrate is converted to ferro-vanadium, the commercial product, a hard, silvery-white alloy of approximately one part of vanadium to two parts of iron together with minor amounts of silicon, manganese, carbon, and aluminum. This alloy has a melting point of 1300 to 1340° C. which is below the fusing temperature of steel or iron, so that it can be absorbed readily in a molten bath of iron. The ferro-vanadium plant of the American Vanadium Co. has a maximum capacity of 30,000 lb. of alloy daily.

Vanadium-steel is employed extensively for special carbon and high-speed tool-steel, for parts of locomotives, automobiles, trucks, submarines, aeroplanes, guns, armor. As would be expected, the use of it has increased greatly since the War.

[Mention should be made of the vanadium produced in Colorado and Utah. In part it is found in carnotite ore and is recovered as a by-product from the production of radium, although it is contained in the ore in much greater quantity than the radium, and in fact the ores were prospected originally for the vanadium. High cost of transportation and irregularity of methods are being overcome slowly in these North American districts. Furnace-men assert that the function of the vanadium in steel-making is to "act as a scavenger" in removing impurities.—EDITOR.]

*Abstract of article by C. J. Stark in the *Iron Trade Review*, October 21, 1915.

The Recovery and Use of Thallium

BY L. S. AUSTIN

The General Electric Co. has found thallium* useful in incandescent lighting, and has need of about 100 pounds monthly, having in the past imported the metal from Germany.

On account of the European war this supply has been cut off and the company has been searching in this country in order to obtain an adequate supply.

Some varieties of pyrite and of zinc-blende contain thallium, and when these sulphides are roasted, thallium, being a volatile metal, deposits with other metals in the bag-house of the silver-lead smelter, and so is capable of recovery. But cadmium is also a volatile metal, and of late this has been recovered by a careful reducing roasting of the flue-dust, and the treatment of the calcine by leaching. From the filtrate is thrown down the cadmium, and, after further clearing of the solution from other cases, the thallium can be precipitated by means of zinc-dust. In the instance above cited, it was present in the solution to the extent of 0.012 to 0.017%. It is worth roughly $20 per pound; cadmium $1.50 per pound.

The use of the metal is so limited, except to supply an assured demand, that it would not pay except in a few instances to undertake its recovery.

*From the Greek *thallos*, green, since the metal burns with a beautiful green flame.

TUNGSTEN means in Swedish 'heavy-stone,' and was at first mistaken for tin ore, until the chemist, Scheele, showed in 1781 that the mineral scheelite contained lime and "a peculiar acid."

Effects of Soluble Components of Ore on Flotation

By AN OCCASIONAL CORRESPONDENT

In concentration by flotation, the soluble components of an ore may play an important rôle. Occasionally ores that are shown by preliminary test to be unsuitable for flotation may be treated by the process after the soluble ingredients have been removed by decantation. On the other hand, excellent results may be obtained on certain ores by flotation in fresh water; but when the water is fouled by successive contact with fresh lots of ore (as is often the case in mill-practice) the results may be far from satisfactory.

This article deals with a determination of the fouling agents in a certain ore, and outlines methods for overcoming such fouling effects. Since all tests were made on ore from a single mine, the results cannot be regarded as generally applicable; however, it is hoped that the experience recorded here may be of some interest to others studying similar problems in flotation.

The tests were made on a silicified-rhyolite ore assaying silver 37 oz., gold 0.15 oz., lead 1%, copper 0.25%, and zinc 1.5%. The principal minerals were argentiferous sphalerite, argentiferous galena, and stromeyerite. The value lay almost entirely in silver. For this reason, only silver assays are here recorded. Sufficient analyses were made to indicate that the concentration of zinc, lead, and copper roughly paralleled that of silver.

Preparatory to making the tests, a large general sample of the ore was ground to pass a 200-mesh screen, and thoroughly mixed. In each test, a 200-gram portion of the general sample was emulsified with one litre of water and 0.05% of crude pine-oil. The mixture was then treated for a half-hour in an experimental flotation machine, consisting of an agitation-chamber connected in such a manner with a concentrate-separation chamber, as to permit of repeated treatment of the tailing. Results in a flotation plant treating this ore roughly checked the work in the experimental machine.

Preliminary tests showed that when the ore was treated by flotation in fresh water, the tailing assayed 13 oz. silver and the concentrate assayed 440 oz. per ton. When the water used in the first test was removed by filtration and re-used on a second test, the tailing assayed 18 oz., and the concentrate 240 oz. When the same water was re-used a third time on a fresh sample of ore, the tailing assayed 27 oz.; the concentrate, 190 oz. Evidently some extremely deleterious substances had been dissolved from the ore. An analysis was made of the water filtered from the third test, with the following results:

Iron (ferric)	Tr.
Iron (ferrous)	0.002%
Aluminum	Tr.
Calcium	Nil
Magnesium oxide	0.012%
Sulphur	0.020%
Manganese	0.001%
Potassium and sodium	0.010%
Copper	Tr.

Most of the soluble minerals were present as sulphates.

The next step was to determine the effect, on flotation, of the various sulphates.

Sodium and potassium sulphates, when added to fresh tests in the proportion indicated in the analysis, yielded a 13 oz. tailing and a 650 oz. concentrate; thus producing a marked increase in the grade of concentrate without deterimental effect on the tailing.

Manganese, magnesium, and ferric sulphates produced no effect when added in the proportions indicated; in larger amounts, magnesium sulphate was harmful and ferric sulphate beneficial.

Ferrous sulphate proved extremely injurious to flotation. When present as above recorded, a 20 oz. tailing and a 240 oz. concentrate were produced. When a small amount of copper sulphate was added to the same quantity of ferrous sulphate, the tailing assayed 25 oz., and the concentrate 200 oz. Evidently ferrous and copper sulphates were the principal fouling agents in the original tests.

It was necessary to devise means for correcting the effects of these sulphates.

First: sufficient sulphuric acid and hydrogen peroxide were added to a charge containing ferrous sulphate to convert the ferrous sulphate to the ferric state. The tailing from this charge assayed 11 oz., and the concentrate 800 oz. With the same amount of acid, but using no peroxide, the tailing assayed 14 oz., and the concentrate 780 oz. Evidently the acid increased the grade of concentrate and also decreased the injurious effects of the ferrous sulphate upon extraction.

Second: efforts were made to precipitate the ferrous and copper sulphate. A test, containing these sulphates in the proportions indicated in the analysis, was rendered slightly alkaline by the addition of lime hydrate. The tailing assayed 12 oz., and the concentrate 450 oz. When sodium hydrate was used in place of lime, the tailing assayed 8 oz., and the concentrate 600 oz. With the iron precipitated by sodium carbonate, the tailing assayed 6 oz., and the concentrate 800 oz. With a combination of lime hydrate and sodium carbonate, the concentrate assayed 800 oz., and the tailing 3 oz. Evidently the use of hydrates and carbonates produces much better results than can be secured by acid. The cost of sodium hydrate and sodium carbonate, and the injurious effects of the latter upon settling and filtration, restricts the use of these chemicals. Lime hydrate, on the other hand, presents a cheap and efficient means for preventing the accumulation of ferrous sulphate in mill-solutions. The

calcium sulphate resulting from the reaction is somewhat detrimental to flotation; a saturated solution yielding a 16 oz. tailing and a 450 oz. concentrate. In ordinary practice the solution would be far from saturated, and the results much more satisfactory.

The lime-hydrate method has been successfully used on this ore in continuous mill-tests. During flotation the alkalinity was maintained as nearly as possible at 0.02 lb. lime-oxide per ton of water. After flotation, half the circuit-water was wasted, the remaining half being supplemented by fresh water at the head of the mill; lime sulphate thus being prevented from accumulating in the solution. For a month during which the process was used, the concentrate from the flotation plant averaged 600 oz., and the tailing 6 oz. This compares favorably with a 20-oz. tailing from gravity concentration and a 12-oz. tailing from flotation in an acid solution. Aside from effecting better concentration, the lime method is cheaper than the acid process and is not injurious to subsequent cyanidation.

When lime is used in flotation, extreme care must be exercised in maintaining the proper alkalinity. The table submitted herewith shows that the best results, both as regards extraction and grade of concentrate, are secured when the alkalinity during flotation is extremely low (between 0.01 and 0.02 lb. CaO per ton of solution). Experiments indicate that alkalinity is beneficial to flotation but that the coagulating effect of high lime upon slime increases the affinity of the slime for the froth, which lowers the grade of concentrate. When the coagulating effect is counteracted by the addition of sodium carbonate, or when sodium hydrate is used in place of lime, an alkalinity equivalent to a half-pound of CaO per ton of solution may be maintained without harmful effects on flotation. Usually a bare alkalinity maintained with quicklime produces equally good results.

In order further to study the effects of copper sulphate on flotation, a solution containing 0.01% $CuSO_4$ was employed in another series of tests. When this solution was used alone the separation was extremely poor, the tailing assaying 32 oz. and the concentrate 100 oz. When sufficient quicklime was added to produce a slight alkalinity, the tailing was reduced to 24 oz., while the concentrate increased to 180 oz. per ton. A further improvement was effected by the use of sodium hydrate, a 340 oz. concentrate and an 11 oz. tailing being secured. This was still far from satisfactory.

An attempt was made next to precipitate the copper as sulphide. By employing hydrogen sulphide in a solution rendered alkaline by lime hydrate, a 6 oz. tailing and a 450 oz. concentrate were obtained. When sodium sulphide and sodium hydrate were used, the tailing-assay was reduced to 3 oz., and the concentrate increased to 700 oz. These results show that the injurious effect of soluble copper may be overcome by the use of hydrogen or sodium sulphide in conjunction with lime or sodium hydrate.

The following conclusions were established for the ore tested:

1. Sodium, potassium, and ferric sulphates are rather beneficial to flotation than otherwise.

2. Manganese sulphate has practically no effect on flotation.

3. Magnesium and calcium sulphates are slightly harmful, while ferrous and cuprie sulphate are extremely harmful.

4. The effect of magnesium and calcium sulphates may be overcome by the use of sodium carbonate in an alkaline solution.

5. The effect of ferrous sulphate can be overcome by the use of sulphuric acid or, better still, by employing quicklime, caustic soda, or sodium carbonate.

6. The effect of copper sulphate may be overcome by the use of hydrogen sulphide or sodium sulphide in an alkaline solution.

7. The use of sodium carbonate, though aiding materially in flotation, is of doubtful utility in plants where the pulp must be dewatered.

8. Lime hydrate is slightly less satisfactory metallurgically than sodium hydrate or sodium carbonate, but the use of it is inexpensive and aids materially in settling and filtering.

Thawing Frozen Ground

A Russian method of thawing bottoms of shafts or pits in perpetually frozen ground is as follows:

Near the excavation is made a large fire-place. A fire is lit, and large stones—over 30 lb.—are put in it. When thoroughly heated they are thrown into the opening, cooling in 6 to 8 hours. They are taken to the surface for re-heating. In the meantime the upper part of the thawed ground is extracted. Then the stones are put in the pit again, the cycle of operations being continuous. A considerable amount of time, labor, and fuel are necessary, but the following advantages are claimed:

(1) The thawing does not prevent the accumulation of any quantity of water at the bottom, but on the contrary favors it, so that the water transfers its heat to the ground to a greater depth than is heated by an open fire; (2) the walls of the pit or shaft are never penetrated, and there is no caving, while in the case of the open fires this is a common and an expensive occurrence requiring extra expenditure in lining; and (3) there is no risk that the wood lining may be fired, which is possible in connection with open fires.

The degree of thawing effected in the ground by stones varies as in the case of fires, from 2 to 8 verchocks (3¼-14 in.) per shift of workmen, depending chiefly on the nature of the ground. The most rapid and easily melted are the poorly coherent marls of river beds, small pebbly conglomerations, and fine sands; and the worst is hard clayey ground, such as pure solid frozen clay and various combinations of clay. These deposits are easily displaced by means of explosives, but there are other kinds of ground such as marley clay with boulders which are difficult to extract either by fire or explosives.

[We refer to this subject on the editorial page.]

The Braden Mill, Chile

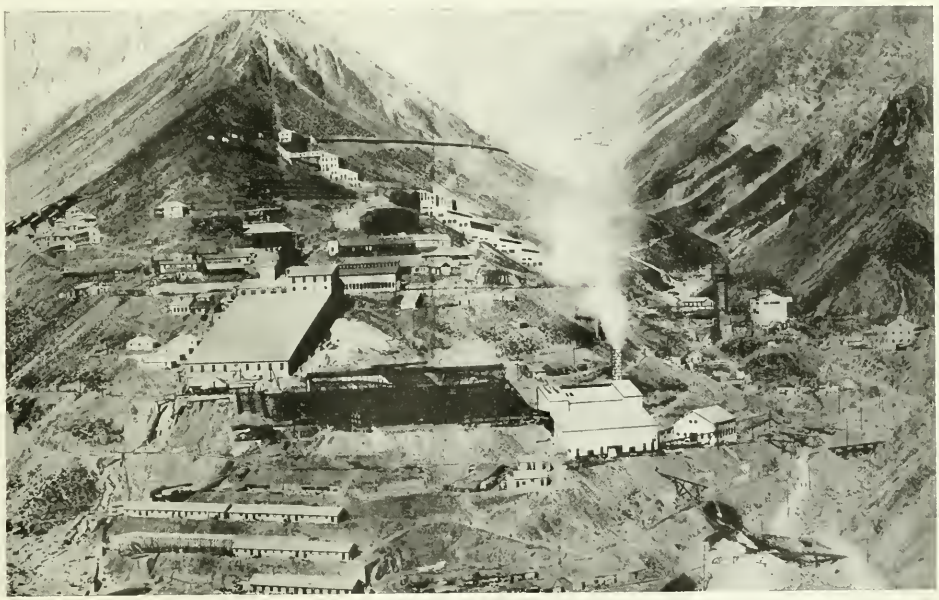
*The crushing and concentrator plants of the Braden Copper Co. are situated about two kilometres west of the mines on the northern side of the Teniente river. The topography is such that full advantage is taken of gravity in the transport of the ore from the mine and in the arrangement of the mill. The difference in elevation between the top of the coarse-ore bins, where the ore is received from the mine, and the bottom of the filter-press plant is 403 ft. The area covered by the entire concentrating-plant itself is 130,000 sqnare feet.

The ore is hauled from the mine to the coarse-ore bins on an electric railroad, and is weighed before it is dumped. These bins have a storage capacity of 2300 tons. Mechanical feeders deliver to a belt-conveyor system, which carries the ore to the crushing-plant. This is divided into two sections having the same number of machines of similar capacities, only one of which will be described. Each of these sections takes half of the stream from the last conveyor of the system. The ore passes over a 1½-in. grizzly, a series of flat-steel bars placed edgewise at an angle of about 45°. The oversize falls directly into a gyratory crusher, while the undersize joins the crusher-discharge which has been reduced to an average of less than two inches. These two products are then crushed to ⅝ in. in a pair of rolls 6-ft. diam. and 20 in. wide.

The discharge of these rolls is divided into two parts, each passing into a trommel. This has diagonal openings, 6 by 30 mm., through which fall the smaller pieces of ore. This portion is carried direct to the fine-ore bins by conveyor-belts. The part that cannot pass through the trommel goes to a 48-in. Symons disc-crusher, which reduces the ore to a maximum size of ⅝ in. The discs are of manganese-steel.

The discharge of the Symons machine passes over shaking (impact) screens with openings 6 by 30 mm. The smaller pieces are shaken through, and are taken to the fine-ore bins by the conveyors previously mentioned. The larger pieces go to two 36 by 15-in. rolls, and the remainder to two more 36 by 15-in. rolls, for re-grinding. The discharge from the latter joins the discharge of the first set of 36-in. rolls, and is elevated and passed over the same screens again. By means of this arrangement all the ore must pass through the 6 by 30-mm. openings of the screens, before it reaches the fine-ore bins preparatory to further treatment.

The fine-ore bins have a storage capacity of 3000 tons. From them the ore is delivered to the concentrator build-



THE MILLS AND SMELTER OF THE BRADEN COPPER COMPANY, IN CHILE.

*By the Mill Staff. Abstract from *Teniente Topics*. October 1915.

ing by means of belt-conveyors. The mill is divided into three units, each with a nominal capacity of 1200 tons per 24 hours, only one of which will be described, as the other two are similar.

From the final belt-conveyor the ore passes over four impact-screens with 25 openings per square inch, making a separation between the smaller particles, (which can now receive their first concentration) and the larger ones, which require further grinding in order to liberate the valuable mineral. These larger particles run from the screens down to two sets of rolls, then to an elevator, the discharge of which joins the fine that has passed the screens. At this point water is added, and the pulp flows to four trommels with screens having the same opening as the impacts. The material that passes through these screens is fed to six Wilfley tables. The concentrate flows to collecting-tanks at the foot of the mill; while the sand, which still contains a large amount of adhering mineral needing further grinding to free it, goes to eight Hardinge conical mills. These are half-filled with pebbles, having a maximum diameter of five inches. They revolve at 28 r.p.m. The oversize of the trommels mentioned is also treated in these mills.

All the discharge is now fed to two drag-classifiers. The sand is concentrated on six tables similar to those at the head of the mill, the concentrate going to the collecting-tanks, and the rejected sand to the next floor of Hardinge mills for still further grinding. On this floor there are six mills, which reduce the above reject or table-tailing to the size required for final concentration. These mills are each fed by a drag-classifier, the slime overflow of which runs direct to the flotation-plants. The whole discharge of the mills is elevated and returned to the classifiers, so that no large particles can escape from the circuit.

The ore has now been ground so that approximately all but 10% will go through a 60-mesh screen. The final concentration is effected by means of the Minerals Separation process. This is done in eight standard M.S. machines, which treat the ore from the three mill-units. Briefly, this process consists in adding a small quantity of suitable oil and sulphuric acid to the finely ground ore, thoroughly mixing them, and then allowing the resulting froth to come to the surface. This froth raises the particles of copper sulphide, leaving behind the particles of gangue material. The operation is carried out in wooden compartments, in each of which is a rapidly revolving agitator, connected with another compartment in front, in which the mixture comes to rest and the float is collected. The material travels from the agitating-compartment to the settler, from the settler to the second agitator, and so on until almost all the mineral content has been extracted. The float from the last two boxes of each plant is very low in copper, and is collected separately and re-treated, this pulp being pumped back to join the original feed of the plants. The sand, from which most of the mineral has now been extracted, is all collected into one launder, passed through a sampler, and then conducted down the valley to the tailing-dam.

The concentrate is collected in concrete tanks at the foot of the mill, from which it is loaded by means of a crane into railroad-cars to be taken to the smelter. The overflow of these tanks, consisting of sulphide slime too wet to be smelted, is run to Dorr thickeners. The thickened concentrate is drained by a Kelly press and an Oliver filter.

The following table gives some interesting data:

Ore treated per man per day, tons	8.5
Kilowatt-hours per ton milled	29.6
Acid per ton milled, pounds	7.00
Tar-oil per ton milled, pounds	2.00
Fuel-oil per ton milled, pounds	0.30
Local pebbles per ton milled, pounds	8.75

On account of the site of the plant, in a foreign country, and consequently the long distance from the main base of supplies, the duties and ocean freight on all sorts of material bring the item of supplies up to 60.4% of the total direct milling cost. The proportion of total cost chargeable to the various departments, for labor and supplies respectively, is shown in the following table; this also gives the proportion of the total direct milling cost that is borne by the different departments:

	Labor, %	Supplies, %
Coarse ore-bins and conveyors	4.07	2.51
Crushing-plant	21.29	16.02
Fine ore-bins, conveyors, mills, rolls and screens	9.02	7.17
Table concentration	7.04	2.97
Hardinge mills	21.98	25.00
Oil-flotation, main plant and re-treatment	22.81	42.58
Concentrate handling	8.33	1.14
Filter-presses	5.46	2.61

The San Francisco Mint

October receipts are reported as follows:

Gold.	Fine ounces.	Value.
English coin	422,323.272	$ 8,730,196.87
Japanese coin	30,129.165	622,825.12
Chinese bars	40,563.009	838,511.82
Australian bars	58,851.725	1,216,573.13
Other sources	256,732.404	5,307,129.75
Total	808,599.575	$16,715,236.69
Silver	96,727.67	47,779.15

Coinage amounted to $590,000 in eagles, and ₱10,000 in one-centavos for the Philippines. At the end of October the vaults contained the equivalent of $340,200,398.77.

Scheelite mining is becoming increasingly important around Atolia, near the line between San Bernardino and Kern counties, California, which is due west from Bakersfield. Both lode and placer mining is in progress. The lode deposits are thought to lie in a belt of granite 30 miles long. Lessees are active, and driving on bedrock under an overburden of 20 to 40 ft. is productive. The Atolia Mining Co., associated with Atkins, Kroll & Co., is now employing 250 men, and is producing 100 tons of scheelite per day, besides buying from lessees. A recent sale of 13 tons of concentrated scheelite brought $42 per unit of 60% WO_3.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

BLENDE is derived from the German *blenden*, to dazzle.

POWER INPUT to a transformer is always greater than the power output because of the losses within it.

WOLFRAMITE is a tungstate of iron and manganese. It is black or brown, resinous, metallic, with a hardness of 5 to 5½ and a specific gravity of 7 to 7½.

HUEBNERITE, or manganese tungstate, named from Huebner, a German chemist, has a hardness of 4½, and a specific gravity slightly over 7. It occurs usually in bladed forms possessing a perfect cleavage, but rarely is in distinct crystals. Its color is brownish-red to black, while its streak is yellowish-green to gray.

LITHARGE has been found a good substitute for lead acetate at Kalgoorlie, Western Australia. At the Perseverance mill the litharge is ground in a pan with quick-lime, in which it is soluble. From the pan the mixture flows to the tube-mill circuit, and then back with the unground sand in the main pan circuit.

WHERE THE LAND about a proposed shaft is flat and no dump is available, a sub-structure of heavy timbers may be built up above the site of the shaft for 8 or 10 ft. The rock hoisted from the shaft may be dumped around it, filling in the timber and rendering it rigid. In time a head-frame can be set upon this sub-structure.

COPPER and its alloys have been used for coins since the earliest records. In the United States silver and gold coins contain 10% copper; 'nickels' contain 75% copper and 25% nickel; pennies contain 95% copper and 5% tin and zinc. In 1914, nearly a million pounds of copper was used in the United States for coinage.

ONE MANUFACTURING FIRM in the United States uses 50,000 lb. of copper annually for bull-rings. About half a million pounds is used each year in making cans. Practically fifty billion pins are made annually in the United States; most of which are of brass containing 65% copper; apparently 5,000,000 pounds of copper is consumed each year for pins.

POTASH is reduced from wood ashes by pouring hot water on them. This produces a lye solution, which is evaporated in shallow pans to near dryness (6% moisture), when the crude salt is shoveled out. This material is calcined in a reverberatory-furnace, where up to 20% of the weight is lost. Some wood ashes contain a high percentage of potash and phosphoric acid.

POWDERED ALUMINUM is in heavy demand for use in explosive shells. When the shell explodes the powder flashes up brilliantly, as magnesium would do, indicating to the gunners where the shell exploded, and even illuminating the object at which aim was taken. Powdered antimony is used for the same purpose, but aluminum is pulverized with difficulty, while antimony can be crushed with ease.

VANADIUM is used in the manufacture of special steels, which contain at least 0.15% of the metal. Discussion has arisen as to whether the vanadium is a scavenger or not, some users holding that with carbon vanadium forms a double carbide of iron and vanadium, promoting the even distribution of the carbon and retarding constitutional segregation, while other users consider that vanadium is never added to steel for deoxidizing or scavenging purposes, but solely as an alloying metal, with the endeavor to lose as little as possible of the addition. The cost of vanadium is too high to allow such losses by oxidation.

MANGANESE-STEEL is used considerably in mining machinery, in such apparatus as crushers, ball and tube-mills and other comminuters, dredges, steam-shovels, stamp-mills, screens, pumps, and many others where the wear is very heavy. The metal is made by adding from 11 to 13.5% manganese to ordinary cast-steel. This increases the ductility of the product, making it tough and resistant to abrasion. The carbon content is 1.25%, and tensile-strength, 108,460 lb. per sq. in. The use of manganese-steel liners in tube-mills has given complete satisfaction. In one plant in Nevada a set of manganese-steel lifting-bars lasts 14 months, and a set of semi-steel liner-plates, 23 months; the consumption of metal was 0.049 lb. and 0.137 lb. per ton of material ground, and pebbles 4.83 lb. Lips for dredge-buckets are made of manganese-steel and riveted on. The tumblers are lined with this metal, and also the revolving-screens. Mine car-wheels give better results when of manganese-steel.

MOLYBDENITE is produced largely in Queensland, Australia, and a recent discovery is reported from the Mt. Perry district, 58.5 miles from the port of Bundaberg. During the quarrying of a quartz outcrop for ballasting a railway, and for use in smelters nearby, years ago, the molybdenite was detected, but remained unworked until last December. At a depth of 55 ft. results have been excellent. The molybdenite occurs in the quartz (rarely in the surrounding pegmatite) in radiating crystal masses. The largest single piece found weighs 3 lb. The quartz in the 'pipe' is remarkably free from other minerals, not even pyrite. A sample of hand-cleaned molybdenite gave 57.7% molybdenum, and 38.7% sulphur. Associated with the molybdenite at the 55-ft. level is a good deal of dark greenish-blue mud, apparently a decomposed chlorite, and this also occurs filling most of the joints in the quartz. According to a late visit of the government geologist, Lionel C. Ball, the Tyrconnel is a mine of great promise.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

Big Profits.—Zinc Sulphide.—New Plants and Labor.—Lead, Pyrites, and Zinc Carbonate.—District Outputs.

Higher prices for spelter and zinc ore in November resulted in a large influx of wealth to this region. Shareholders in companies have clamored for prompt distribution of profits. One concern paid two 10% dividends in a month; another 140% for the year; and another 85% for 1915.

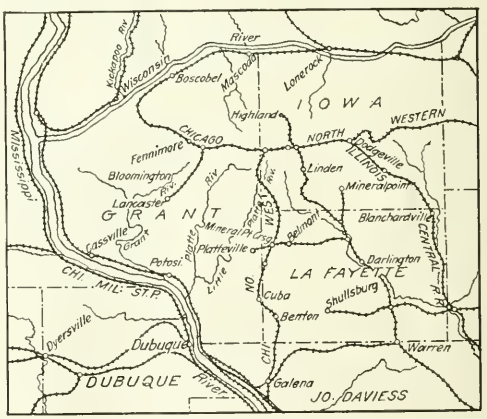
The turn-in of crude ore was high, and a greater amount of finished material from the local refineries cleared direct for smelters than in any previous month. Top grades cleared $115 toward the close of the month, and the range held well at $105 to $110 per ton with no restrictions on all grades from the highest to the lowest. This resulted in an almost abnormal influence on miners, many of whom broke away from pay-rolls with which they had been long associated, to try mining on their own account. Many long abandoned low-grade mines were reopened, and the poorest ores commanded prices that meant large profits to the small operators; 50% material selling as high as $75, 45% at $50, and 40% at $45 per ton. Even a quantity of lower grade was disposed of readily to the separating-plants. The capacity of these was greatly enlarged by the starting of three new plants at scattered points, enabling custom-plants to buy more freely from independent operators, many of whom had been hoping for an outlet for low-grade material. Double shift became the rule at all mines where sufficient labor could be secured. Separating-plants were operated at maximum efficiency full time. Storage-bins were cleaned out completely.

A year ago this region was lightly regarded by leading operators, but now it is a Mecca for mining men, and capital is flowing into the field from all parts of the United States. Hotels are full of strangers. The two leading railway companies are considering routes for two branches into the centre of the field. At New Diggings district, the Wisconsin Zinc Co. fired up a new ore refinery on November 20, coating $100,000 or more. Another new separating-plant was started at Galena for the Great Western Mining Co., constituted mainly of railway officials connected with the Great Western Railway Co. Another refinery is being constructed at Galena, on the Illinois Central railway by the Galena Refining Co., incorporated under the laws of Illinois organized by leading officials of R. W. Hunt & Co., of Chicago. Seven acres of land was purchased in the city limits, and the new plant, which it is proposed shall be put into commission in January, is built to show a new method of electrolytic zinc-ore separation that it is said will supersede all present methods. The New Jersey Zinc Co. completed a re-modeled acid works at Mineral Point, and commenced shipping a 25-ton tank-car of commercial sulphuric acid per day. In the New Diggings district, where less than two months ago under 500 men were employed in mining, 1000 men were at work on December 1. Labor conditions are good. At one or two points threatened strikes were quickly averted by cool heads, to the material gain of the men. In the Benton district several operators pooled issues, and are now engaged in the building of macadam roads to enable outlying producers to ship all the year round.

Sales of lead ore increased, but were light. Ore climbed steadily from $62 and $64 to $70 and $75 per ton, receding again to $65 and $70, at which figure the month closed, with sellers reluctant to let go. Some ore, however, was carried over.

Producers met with a more insistent demand for pyrites, and slight gains were recorded in price, but little crude ore was offered, and such as did clear came from the separating-plants in the field, which are arranged so that this mineral can be conserved. Much of this ore is now finding its way into the bins of powder-manufacturing establishments.

Miners of carbonate zinc ore were surprised to get as high as $80 per ton for 40% product. The demand for ore stimulated the cleaning-up of old dumps. About 1500 tons or more of dressed ore, ready for prompt shipments, awaited a demand from buyers at the close of the month, but peculiar conditions confront the miners of this class of ore. The price is too high to pay where the ore is used in the manufacture of zinc oxide, and not high enough in zinc content to be used for spelter in this form.



THE ZINC REGION OF WISCONSIN.

Deliveries reported by districts were as follows:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrites, pounds.
Benton	13,166,000	165,000	.....
Mifflin	5,664,000	80,000	.....
Cuba	3,656,000	.....	1,597,480
Galena	3,564,000	65,100	81,000
Platteville	3,494,000	.....	1,490,000
Hazel Green	2,824,000	64,200	.....
Linden	2,590,000	80,000	389,800
Shullsburg	1,094,000	.....	.....
Highlands	988,000	.....	.....
Dodgeville	222,000	.....	.....
Potosi	134,000	.....	.....
Mineral Point	64,000	.....	.....
Mineral Point Zinc Co.	3,723,700	.....	.....
Total	41,183,700	454,300	3,558,280

The gross turn-in of crude ore from all mines exceeded 31,000,000 lb., and net deliveries direct to smelter 20,327,700 lb. Less than seven years ago the total shipments for a single given month would scarcely exceed 2000 tons.

Sales were distributed among the following smelter concerns: Mineral Point Zinc Co., 4778; National Separating Works, 5162; Wisconsin Zinc Roasters, 2353; American Metals Co., 1196; M. & H. Zinc Co., LaSalle, 1067; Grasselli Chemical Co., 1007; Granby Mining & Smelting Co., 818; Illinois Zinc Co., 643; Lanyon Zinc Co., 721; and American Zinc Co., 352; also the Picher Lead Co., and several roasting establishments.

TORONTO, ONTARIO

Developments at Deloro, the Plenaurum, Tisdale, Porcupine, Tashota, and Ogden.—Molybdenite.—Steel.—Reports.

Interests allied with the New Jersey Zinc Co. have taken an option on the Dobie and Maidens-MacDonald groups of claims in Deloro township, and early next week will inspect the Davidson claims in northern Tisdale.

The Plenaurum shafts have been de-watered, and Mr. Beidelmann, representing D. Lorne McGibbon and the La Rose interests, has commenced sampling the property. The Porcupine Excelsior Mining Co., which has recently purchased the Pope claims in southern Shaw township, has its two-stamp mill at Sherrill's landing on the Redstone river, and as soon as the river freezes sufficiently will erect it on the property. Some remarkably rich specimens of free gold are on exhibition from this property at the Goldfields hotel at Timmins. This company has now completed its winter road to Porcupine, and is ready to take in supplies when the sleighing is good.

The Porcupine Contact Mining Co. is resuming operations at its claims at Tisdale, half a mile north of the Dome.

Porcupine as a whole is continually increasing in activity, and several representatives of financial groups in the United States are there looking for mining properties. This, with the excellent results obtained by the various producing properties, has resulted in a fairly active share market.

Another discovery of free gold with tellurides has been made at the Devaney claims in the Tashota Lake district on the trans-continental railway.

The Hayden Gold Mines, Ltd., in Ogden township, is crosscutting south from its shaft to intersect any veins between the shaft and the contact between the quartz-porphyry and the schist; also to the north to the contact with the diabase-dike.

An interesting discovery of molybdenite has been made on mining claim P 7171 in Deloro township, in a jaspillite zone. The jaspillite has undergone considerable shearing and fracturing, and the fracture-planes have been impregnated with secondary quartz associated with sulphides of iron and copper. The molybdenite occupies a zone about five feet wide, and is associated with the secondary quartz in crystal aggregates ranging from $\frac{1}{8}$ to $1\frac{1}{2}$ inches diameter.

The requirements of the shell industry have resulted in great activity by steel manufacturers. All steel plants are working to full capacity, and several are making additions.——The Dominion Steel Corporation has started a new merchant-steel mill.——The Steel Co. of Canada will enlarge its plant at Hamilton, Ontario, by the construction of three new open-hearth furnaces and two forge-shops, and will extend its blooming-mills.——The plant of the Northern Iron & Steel Co. at Collingwood, Ontario, which has been idle for some time, will be re-opened under new management.——There are now 320 plants in Canada engaged in the manufacture of shells or their component parts. According to a statement by Alex. Bertram, formerly chairman of the Canadian Shell Committee (which body has just been superseded by the Imperial Munitions Board), the shell orders from Britain now in hand call for 20,000,000 shells, worth approximately $220,000,000. In addition, further orders to the amount of $180,000,000 are anticipated before the end of the year. The amount of material required to fill these contracts, present and prospective, includes 80,000,000 lb. steel, 45,000,000 lb. copper and brass, and 1,500,000 lb. tin. To aid in securing adequate supplies to keep the plants busy the Government has appointed a commission to inquire into the supply and sufficiency of raw materials in Canada required for the production of munitions of war, and the best methods of conserving them. The Commission includes Thomas Cantley, president of the Nova Scotia Steel & Coal Co., chairman; George W. Watts, Toronto, E. Carnegie, Welland, Ontario, Robert Hobson, general manager of the Steel Company of Canada, Hamilton, Ontario, the Hon. W. E. Edwards of Ottawa, and George C. Mackenzie of the Canadian Department of Mines, Ottawa.

The sixth annual report of the Hudson Bay Mines Co., for the year ended August 31, 1915, has been published. Work at Cobalt was confined to No. 2 workings. Shaft-sinking, exploration, and diamond-drilling was done, the last being satisfactory in the conglomerate. Assessment work was done at Kirkland Lake. The Dome Lake property was an active producer.

The Seneca-Superior Silver Mines, Ltd., of Cobalt states that its dividends in 1915 total $335,219, including 10c. per share (478,884 issued out of 500,000 authorized), on December 15. The total in three years is $981,212, equal to 205%. On November 20 the cash on hand amounted to $240,000. Seven cars of ore are in transit. The cost in October was $3.55 per ton, or 4.8c. per oz. of silver, against $4.25 and 9.6c. in June.

WASHINGTON, D. C.

Leasing Proposals.—Mining Laws.—Bureau of Mines.

The leasing bills have made an early appearance in Congress, and one of the earliest is that of Representative Mondell of Wyoming, who is a man of long experience in Washington and of some importance. He is a Republican, and therefore of greater influence when this party is in power. His advocacy of leasing shows an important trend, which is emphasized in this case by the fact that he belongs to the anti-conservation group. His bill provides for the leasing of coal lands, and permits the Secretary of the Interior to grant licenses giving to holders the exclusive right to prospect and explore for coal on vacant public lands, and to execute leases authorizing the lessee to mine and remove coal from such lands. No license shall pertain to more than 3200 acres, and no lease shall pertain to more than 2560 acres and all the areas shall be reasonably compact in form, and conform to the public surveys. No prospecting period is to be issued for longer than three years. Rental and royalty on coal mined is part of the leasing scheme. A monopoly in whole or in part in the trade in coal is forbidden. Inspection of the mines by the Department of the Interior is arranged for. The United States also reserves for itself a preference right to take as much of the product of any mine as may be necessary for the army, the navy, and the revenue-cutter service, of course for a remunerative price. Seventy-five per cent of all the money derived from licenses and leases granted under the act is to be paid to the State within which are situated the lands so leased, the money to be utilized for the construction and maintenance of roads, the establishment and maintenance of schools, and other purposes that the legislature of the State may provide.

A meeting of delegated mining men is to be held in Washington on December 16 to urge Congress to appreciate the necessity of revising the mining laws. Three sessions are to be held on that day. The details are almost as elaborate as a convention. The proposed legislation is to be thoroughly discussed, but without needless detail to bewilder Congress.

The first annual report of Van H. Manning, director of the U. S. Bureau of Mines, has been presented. It discusses the large industrial achievements by American manufacturers, the large sums of money saved by utilizing previously wasted material, and the new industries created to manufacture what formerly has been imported, and the consequent growing industrial independence of the United States. Mr. Manning says that the Bureau is trying to find new and profitable methods for treating the millions of tons of unworked low-grade ores in the West.

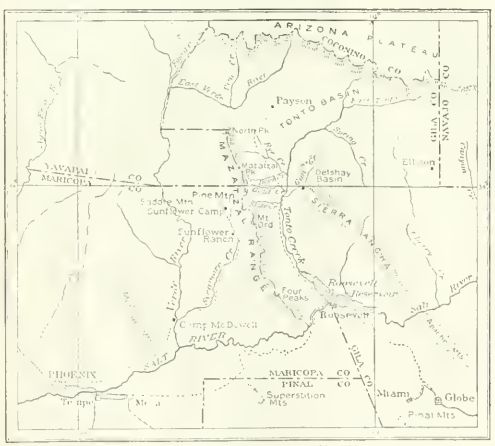
THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

Prospecting for and development of tungsten properties in this State is on the increase. During the past few weeks the State Bureau of Mines at Tucson has had inquiry from responsible syndicates in the East desiring to purchase tungsten mines, and the Bureau announces that it will be pleased to communicate the details of any tungsten properties that may be called to its attention.

The quicksilver deposits of the Mazatzal range, in the Tonto national forest, are described by F. L. Ransome in Bulletin 620-F. of the U. S. Geological Survey. The area is a well-defined ridge in central Arizona, about 40 miles long. At each end are peaks 7600 ft. high. The quicksilver deposits occur in a strip of country six miles long, north-eastward across the range near Pine mountain. All of the claims are



PART OF CENTRAL ARIZONA.

in the Sunflower district, which lies at an elevation of 4350 ft., 70 miles from Phoenix by road and trail. Freighting costs $40 to $50 per ton. The publication describes the routes of getting there. Cinnabar was found in October 1911 by E. H. Bowman. His and other claims were purchased by the Sunflower Cinnabar Mining Co., organized in February 1913, with a capital of $1,000,000. A retort-furnace was erected in September of that year. The geological features are detailed. The deposits are lodes in schist. Some chalcopyrite, specularite, and native mercury are found. The lodes do not outcrop conspicuously, and are more commonly marked by a slight depression than by a ridge. Claims in the Maricopa County belt have a length of 24,400 ft., and in the Gila County belt, 25,500 ft. A good number of adits have been driven. The lodes are persistent, and prospects are very promising. Considerable quantities of 2% ore can be obtained with moderate sorting, but better reduction methods must be arranged.

According to P. E. Joseph in Bulletin No. 5, Mineral Technology Series No. 3, of the Arizona State Bureau of Mines, molybdenum is found in limited quantity in many widely separated localities, namely Helvetia, Madera canyon, Providencia canyon, Duquesne, and all along the international boundary. Helvetia is situated 27 miles south-east of Tucson, in the northern part of the Santa Rita mountains on the west slope, at an elevation of about 4300 ft. Here, molybdenite is found in the Leader and the Ridley mines. The former is situated east of the town at an elevation of about 7400 ft., near the contact of the altered Paleozoic limestone with underlying pre-Cambrian and post-Carboniferous granite. The molybdenite occurs in lenses, irregular bodies, or in masses and crystal aggregate embedded in a dull-brownish and greenish to yellowish, mineralized, garnetiferous, silicified-limestone and quartz, which rock has resulted from contact metamorphism of the intrusive granite with the limestone. The molybdenite is mostly fine grained, but in places it is found in crystals ranging up to one-half inch and more in diameter. In the Ridley mine, situated to the south-west of the town, at an elevation of about 4060 ft., some fine-grained molybdenite is found in the lower portion of the vein, in a band composed of sericite mica, quartz, pyrite, and varying in width from one-eighth to four inches. Madera canyon drains the north-eastern part of the Old Baldy section of the Santa Rita mountains, about 10 miles south-west of Helvetia, and 35 miles south of Tucson. In the foothills part of its course, where the creek crosses the Pima-Santa Cruz county line, are found the McCleary prospects. The country rock is pre-Cambrian (?) granite. It has been fractured by dynamic disturbances, and along the resulting joints and fault fissures occur quartz veins. In these quartz veins molybdenum is found in heavy, thick masses, quite clean and pure. In Duquesne, and along the international border, molybdenum does not occur in sufficient quantities to be of commercial importance. In the Mammoth gold mine, at Shultz, Pinal county, wulfenite occurs abundantly, sometimes in aggregations of crystals, weighing many pounds. For many years the Mammoth, which was a famous gold mine, has been accumulating tailing on the dump, which has been picked over, and for three years has afforded the entire output of wulfenite marketed in this country. The Troy Manhattan Copper Co. has discovered sufficient wulfenite to warrant the erection of a 40-ton mill for concentration of the molybdenum ore, and a plant for treating the concentrate. Wulfenite, in association with some vanadinite, is found in the Old Yuma mine, about 20 miles northwest of Tucson. Molybdenite is also found in disseminated ores of Miami, in copper ores of Clifton-Morenci district, with copper in Hualpai mountain, Maynard district, in Pinal county in ores at Ray-Kelvin mines as original mineral. Recent newspaper reports state the discovery of many molybdenum deposits in various parts of the State. However, these have not yet been sufficient developed. Most of the deposits in Arizona occur under geological conditions favorable for the molybdenum, and it is very possible that further development may make many deposits of commercial value. An important point in the selection of deposits for development is the absence of chalcopyrite, which reduces the market value of the ore, due to the difficulty of separating the chalcopyrite from the molybdenite.

Gila County

Instruction in first-aid has been resumed at the Old Dominion, with Orr Woodburn, formerly with the U. S. Bureau of Mines, in charge. Last year over 400 men were trained.

Greenlee County

It has been alleged that the Arizona, Detroit, and Shannon copper company's relief camp at Duncan was a refuge for strike-breakers, and that the Hon. Chas. G. Harris, adjutant-general of Arizona, had made certain remarks about the company's operations. This led to correspondence between the managers, Norman Carmichael, M. H. McLean, and J. W. Bennie and Mr. Harris, the latter giving his views of the situation, and the managers replying in strong terms to him for his connection with the strike, also denying that strike-breakers were in camp.

Mohave County

Mining developments at Oatman are briefly discussed by J. Nelson Nevius in the November *Mining and Oil Bulletin* of the Chamber of Mines and Oil at Los Angeles. The notes are well illustrated. The mines mentioned are the Tom Reed, Gold Road, United Eastern, United Western, Big Jim, Black Eagle, Telluride, and Sunnyside. The topography east of Oatman is rough, due to faulting. Volcanic 'necks' are a feature of the area.

While cutting out a station at 400 ft. in the Big Jim mine on November 27, ore similar to that in the Tom Reed and United Eastern was cut.

At a depth of 1175 ft. in the Tom Reed the vein is 6 ft. wide, assaying as high as on other levels.

Ont at Yucca the Yucca Tungsten Mines Co. has 40 men constructing a road to its property. A mill of large capacity is to be erected. A good deal of tungsten ore occurs in the district.

Another good ore-shoot has been cut at 530 ft. in the Boundary Cone.

Pinal County

The Ray-Hercules mine has commenced shipping carbonate ore assaying 7.27 to 7.58% copper; the dumps contain 1000 tons. Drills are now searching for barren ground in which to sink the main shaft. Drill-hole 28 has found 145 ft. of 2% ore from 475 to 620 ft. depth. The company has $975,000 in its treasury at Boston.

CALIFORNIA

Amador County

The South Eureka company distributed $20,998 in November, making $230,988 for 11 months.

At the Allen copper mine near Ione the water is being coped with easily at 500 ft. Three shifts are working.

Butte County

The California Gold Mines Co. has been organized at Salt Lake City to operate the Forbestown Consolidated, with a capital of 1,000,000 shares at 5c. each. At the Gold Bank mine 20 stamps are at work.

Mariposa County

The Mariposa Commercial & Mining Co. is being sued by G. W. Langan for $1,500,000, involving title to the Mt. Bullion property, the Mariposa mine, and the site of the town of Mt. Ophir. It is alleged that the company failed to sell the properties after agreements to this effect had been arranged and the first payment made. The price for 44,386 acres was $1,000,000.

Plumas County

(Special Correspondence.)—On Jamison creek, about one mile south of the town of Johnsville, and about ¾ mile south of the Plumas-Eureka mine, are situated the Jamison Mining Co.'s properties. The main vein was discovered in 1889 by placer miners working the gravel deposits in the bed of Jamison creek. The ownership, however, has long since passed from the original locators into the hands of Eastern people, chief among whom are the Burnhams, of the Baldwin Locomotive Works, the Corbins of the P. & F. Corbin Lock Co., who have extensive factories at New Briton, Conn., the Distons of the Diston Hardware Co., and the Cheyney family of Philadelphia. The vein averages about 9 ft. in width, and is composed of white quartz, which is very brittle and easily milled, and contains at depth a considerable proportion of sulphides. It has been worked for several thousand feet along its strike, although the greatest depth at which ore has been extracted is not over 500 ft. The average gold-content does not exceed $3.50 per ton. However, because of the uniform width of the vein, and the fact that the gold is remarkably evenly distributed through it, the expense incidental to handling waste and sorting is eliminated, so that the extraction of the ore can be done on an

THE JAMISON MINE AND MILL, PLUMAS COUNTY.

economical basis. The strike of the vein is north-west and south-east and the dip about 26° toward the west. In 1896 a 20-stamp mill was erected a short distance from the collar of the main shaft, and has been operated practically every season since that time. The ore is trammed by car from the mine to the mill, where it is dumped onto grizzlies. The fine material is delivered directly into a bin, from which the stamps are fed, and the larger pieces pass onto a platform from which they are shoveled into a crusher. After passing a 50-mesh screen the pulp from the stamp flows over copper plates for amalgamation. These plates are of unusual size, 5 ft. wide by 20 ft. in length. The mill treats about 68 tons per day. At the present time no attempt is made to save the tailing; frequent assays show that it is worth less than 50c. per ton. Power for operating the mill, hoisting, air-compressors, dynamos, etc., is furnished by Pelton water-wheels. Water comes from three lakes, (Grass, Jamison, and Wades), the nearest of which (Grass) is situated about 1½ mile south of the property, and at an elevation of 400 ft. above the mill.

Johnsville, November 22.

Shasta County

(Special Correspondence.)—Construction of the Gardella dredge on Clear creek is progressing steadily, and the management expects to start operations early in March. Delayed shipments of lumber have interfered with rapid construction. ——The old dredge of the U. S. Dredging Co. has been moved to the Perry Marks farm, near Redding, and is about to start work on promising ground.——The Shasta Dredging Co. has completed an excellent camp at Gas Point, and is dredging a large gravel deposit, parts of which are rich. Approximately 700 acres is available.

The Victor Power & Development Co. has paid the final installment of $35,000 on the price of the Midas group, at Harrison Gulch. The total price is said to have approximated $125,000. Vigorous operations are proceeding in the Midas mine, and work is to be more aggressively pushed in the Gold Hill and Bonanza properties. C. D. Jackson is manager, and J. A. Sharp, of Red Bluff, president.

Redding, December 6.

Siskiyou County

(Special Correspondence.)—The Big Cliff Mining Co. has completed its new sawmill and will have it running in a few days. The first lumber will be used in construction of the 7700-ft. tramway from mine to mill-site. Building of a mill and numerous surface structures will be rushed as soon as weather permits, and the management expects to be in a position to produce largely early next July. Considerable ore has been blocked out. M. T. Olsen is manager. The property is situated on south Russian creek.

Important quartz and placer developments are reported from the Sugar Hill mine, at Fox creek. A series of shoots ranging from two to six feet wide has been uncovered in a porphyry dike, the quartz being of good milling grade. The old gravel-channel has been intersected and an adit has been started to open the back channel.

Shipments of high-grade ore are being made to the Johnson mill from the Oom Paul mine, at Oro Fino. A vein of milling ore has been cross-cut 12 ft., and a good quantity is exposed. The vein was uncovered in the foot-wall of the narrow vein the former owners worked. W. R. Renfrew is managing owner.

Dan Malloy, owner of the Malloy quartz mine at Tanners peak, near Sawyers Bar, has erected a small stamp-mill, and expects to start crushing soon. Considerable medium-grade ore is available.

Etna Mills, December 13.

The McKean mine has closed for the winter. Developments were satisfactory. A mill and cyanide-plant are contemplated by the owner, Mr. Kenney. The mine is in the Callahan district.——Adjoining the McKean is the Hurzey, where some good ore has been opened.

Trinity County

Owing to a dispute among the shareholders of the Trinity Consolidated, its placer properties have been leased; that at Douglas City to C. H. Tarpley, and that near Weaverville to Otto B. Haas.

Four giants are sluicing at Lagrange and there is plenty of water.

The examination of the Globe Consolidated at Dedrick has been completed by Samuel W. Cohen of the Crown Reserve company, Cobalt, Ontario. There is considerable snow around the mine and mill at present.

Tuolumne County

(Special Correspondence.)—Chas. Helman of the El Oro Dredging Co., Oroville, has taken over the Dondaro Yankee Hill gravel area. The company expects to erect a dredge of large capacity.

The Corrall Gold Hydraulic Co., under the management of Chas. S. Young of Hermosa Beach, is taking over the gravel claims east of Columbia, and will probably equip it for hydraulic mining. The property consists of 100 acres and includes the Rehm, Bacigalupi, and Hastings land. H. M. Gorman of Los Angeles is interested with Mr. Young in the scheme.

A new compressor is to be installed at the Hope mine, east of Sonora. The superintendent, Mr. Weston, is also making other great improvements. Some good ore has been extracted lately, and prospects seem good.

Work at the Rawhide mine near Jamestown is progressing well. The electric hoist and head-frame are in place, and the shaft cleared and timbered to water-level, which is about 60 ft. from the surface. On account of the lack of water they are unable to secure electric power to operate the hoist, which delays much further work in this line. A large compressor was delivered at the mine November 31 and electric pumps are expected to arrive shortly.

Blackburn, Stage, & Macomber have leased from the Black Oak Mines & Mill Co. of Soulsbyville, the Live Oak mine, which is on the south-west part of the Black Oak property. The old shaft has been cleaned out and a steam hoist and compressor installed. At a depth of 40 ft., in clearing the shaft, they cut a vein of high-grade ore, averaging from 2 to 3 ft. in width, and worth from $30 to $90 per ton. This ore is now being treated at the Black Oak mill. Prospects for a large production in the near future are very favorable.

W. J. Loring and party were in Sonora, last week, and visited the Dutch-App mines; great improvements are planned for these properties in the near future.

Sonora, December 1.

COLORADO

Boulder County

Two recent shipments of tungsten ore from the lease of the Short Bros. and another near Nederland returned as follows: 1036 lb., containing 49% WO_3, $1499 per ton; and No. 2, 5000 lb., 20.70% WO_3, $476 per ton. After paying 15% royalty to the Primos company the net profit was $1666.

The Primos Mining & Milling Co., the largest tungsten ore producer in the Boulder district, is to cancel all leases on January 1 for the purpose of increasing the royalties.

Clear Creek County

Miners in the Georgetown district have had trouble in getting a market for their zinc ore, but the Chamberlain Ore Co. announces that it will now receive the ore at its sampler.

The Princess of India adit is to be extended into Columbia mountain, and is expected to cut nearly all the best veins in the Silver Creek district.

Tungsten ores occur in the north Empire district, and when the weather improves prospecting will commence.

Gilpin County

The Colorado-Gilpin Gold & Radium Mining Co. has been organized with a capital of 1,500,000 $1 shares to operate the German Belcher property. The mines produce uranium, gold, and silver ores, and have been closed on account of local difficulties. The officers are W. Wright, president and general manager; H. F. Hoffecker, vice-president; Robert R. Gramer, secretary and treasurer; Forbes Rickard, consulting engineer; and Harry Willis, superintendent.

The new treatment-plant of the American Metals Producing Co. at Black Hawk will be ready to receive sulphide ores in January; it should be a boon to local miners. G. W. Adams is in charge.

Rich copper-gold-silver ore continues to be opened at 700 and 1000 ft. in the Carr mine on Bobtail hill. Arthur Most is manager.

Lake County (Leadville)

Pumping is in full swing again at the Penrose shaft of the Down Town mines.——Rich gold ore has been opened in the St. Louis adit; one pocket yielded 180 lb. of it. A good deal of zinc sulphide ore is also being extracted.—On No. 3 level of the Big Four 1 to 1.5 oz. gold ore is being opened.—Lessees at the Ponsardin, Pilot, Nisi Prius, Little Ellen, and others are getting satisfactory returns.

Ouray County

For the quarter ended September 30 the Camp Bird reports as follows: development, 1173 ft.; tons of broken ore in stopes, 7711 tons; ore treated, 8110 tons; revenue from bullion and concentrate, $291,786; operating charges, $86,121; profit, $160,000; also $48,000 profit from the Santa Gertrudis of Mexico. A dividend of 24c. per share was paid on November

30. On No. 7 and 9 levels some small shoots of rich ore were opened. Ore reserves contain an estimated profit of $275,000, an increase of $75,000. The October output gave a profit of $53,000 from 2730 tons of ore. It is rumored that the company is to drive an adit 9000 to 11,000 ft. from the mill to the present mine workings. This work has been contemplated for some time.

Park County

A number of Leadville men are leasing at the London mine, and 75 men are employed at the South London. The monthly output is 250 tons of 10-oz. gold ore. Prospects are excellent, and more men are to be taken on.

Summit County

An extension of dredging operations will mark future work at Breckenridge. Ground near Gold Hill is being drilled by the Tonopah Placers Co., so is another area four miles down the river by Mark G. Evans.

Teller County (Cripple Creek)

The Roosevelt drainage-tunnel was advanced 291 ft. last month. The ground was hard, and a soft dike had to be timbered. The face is 580 ft. from a point under the Elkton shaft, which is 1450 ft. deep. The flow of water is 15,400 gal. per minute.

The El Paso company and lessees produced 2100 tons of $18 to $20 ore in November. This was treated at the Golden Cycle mill at Colorado City.

On December 17 the Portland company will pay an extra dividend of 2c. per share, equal to $60,000. The total for 1915 is $360,000, and $10,117,080 to date. Grading has been started for the new sampling-plant, which is to be a duplicate of the one at Colorado Springs.

The Rubie and Lafayette mines and dump ores at Bull hill are to be treated in a new cyanide-plant being erected by the Rubie Mining & Milling Co. The mill, to be called the Worcester, will be of 30-ton capacity.

IDAHO

Shoshone County (Coeur d'Alene)

Mining and milling in the Pine Creek district will not be delayed by winter. The wagon-road is in good condition. Good work is being done at the Highland-Surprise (lead-silver), Northern Light (lead-silver-zinc), Yankee Boy (silver), Brown-Fennell (antimony-silver), Coeur d'Alene Antimony, Polaris, and Wisconsin. At the Coeur d'Alene the new mill is working, and 40 men are employed.

According to the state mine inspector, Robert N. Bell, the ore production of 1915 in the Coeur d'Alene, regardless of serious checks due to smelter contract troubles, will eclipse any previous record, not only in value but in the tonnage shipped. The largest lead producers this year, which include the properties covering the deepest developed ore channels of the district, are in splendid shape to maintain the prevailing rate of output indefinitely, provided the market is satisfactory. They already have discounted previous pessimistic estimates of their persistency at depth. He considered that the most gratifying result of the year in the Coeur d'Alene is the expanding ore resources of the region and the appreciation of the ore-bearing possibilities of the Prichard formations, which have the widest distribution of any of the district's sediments. He has been an ardent defender of the ore deposits in this formation for the last eight years, and thinks that their continued development will result in expanding the productive area of the Coeur d'Alene not less than 100%.

The Empire Copper Co. is installing a 14-drill air-compressor; the motor to drive it and the receiver are already on the ground, and the concrete foundations were put in last week. The compressor is a two-stage belt-driven Sullivan, with intercooler. Development work at the mine will be rushed as soon as the power-line is completed, which the Washington Power Co. is constructing from Cataldo, six miles distant.

Owyhee County

During the past season, Olson, Kimerlin, and Grete extracted from the old Trade Dollar workings of the Black Jack lease 48 tons of ore which yielded $41,000 net.

MICHIGAN

The Copper Country

(Special Correspondence.—There is a renewal of interest in the work at the Lake copper mine. This property was placed on the market at the time of the last boom. Its high-grade ore brought about exploration work in adjoining property. Four months ago the mine was reopened under the management of Elton W. Walker, who made such a change for the betterment in the conditions at the Mass Consolidated, and has placed that property on a paying basis. At the present time Lake is shipping ore at the rate of 8000 tons per month, this point being reached at the close of the month of November. Shipments for November were 6500 tons. The yield during November was better than 40 lb. per ton in mineral, which insures better than 25 lb. in refined copper. The interesting point at present is that more than half of the drills are working in places that were abandoned during low copper prices. A good deal of mass copper is also being extracted.

Owing to encouraging developments in the South Lake, there will probably be a resumption of work at the Adventure.

Returns from the Mohawk have been so good that a $7 dividend is expected in January. The average yield of refined copper is 21 lb. per ton of ore. Costs are lower. Development generally is excellent.

Houghton, December 8.

MISSOURI

Jasper County

The extreme northern part of the Webb City district has been practically idle for nearly seven years, but is now being pumped out. Ore occurs at 140 ft. Several mills are contemplated.

Several year's accumulation of slime from the old South Oronogo mill is to be treated in a new sludge-mill. The material will be collected by scrapers, elevated, screened, and passed over coarse and fine tables. A 35-hp. gas-engine will drive the plant. About 4% blende is expected to be recovered.

For over $100,000 the Googie zinc mine at Prosperity was sold last week by J. F. Haley and others to the National Zinc & Lead Co. of Boston. The deal includes a 200-ton mill. Ore occurs at from 171 to 185 ft. depth.

A 200-ton mill is being constructed at the Crown Nest mine at Duenweg, and one of 300-ton capacity near Lincolnville station by the Sambo company. The old Jack Harvard custom plant is to be changed to a tailing-mill by George Meese and others.

MONTANA

Silverbow County

During November the Butte & Superior mill treated 52,430 tons of ore yielding 15,050 tons of concentrate, containing 16,000,000 lb. zinc. The pay-roll was $190,000.

The Czarroman claim and the Travona fraction adjoining and south-west of the Emma mine at Butte has been purchased from the Montana Realty Co. by the Anaconda company for $225,000. The Emma lode runs through these claims; the ore contains zinc.

On December 8 a test was made at Janney, near Butte, of the new electric locomotives of the Chicago, Milwaukee & St. Paul line. The grade is 2%, the steepest between Deer Lodge and Three Forks, a distance of 113 miles. Two locomotives easily hauled 48 loaded cars, equal to 3000 tons, at 16 miles per hour.

NEVADA

Clark County

The Yellow Pine district is very prosperous at present.——The Yellow Pine Mining Co. is shipping 1500 tons of zinc ore and 200 tons of lead concentrate per month. Good ore has been opened at 800 ft. depth. Seven cents per share was paid on November 10, making $300,000 for the year.——The new 40-ton dry concentrator at the Anchor commenced on November 15 using the Stebbins machine.——The Potosi is shipping 900 tons of zinc carbonate per month, the Green Monster 300 tons, the Sutton 150 tons, and the Bonanza 250 tons.——The New Christmas Con. Mines Co. will erect a wet concentrator. ——A number of other mines are producing.

Esmeralda County

A new vein has been cut on No. 3 level of the Jumbo Extension. Assays have given up to $63 per ton. The development is considered of importance. The shoot can be worked from the Velvet shaft. The daily output of the mine is 100 tons.

At the Florence a new 75-ft. head-frame has been erected, new ore-bins, and new skips installed. Development has been resumed at 250 and 530 ft. At the old Florence Goldfield mill-site preparations have been started for the erection of a 150-ton flotation-plant. The Nevada Metal Extraction Co., is composed of Nevada metallurgists and mining men, headed by F. A. Mead. A three-year lease has been secured on the Florence dumps, which contain 55,000 tons, mainly from old leases. Janney machines will be used.

Humboldt County

The president and general manager of the Nevada Packard Mines Co., Mark Walser, reports the finding of seven feet of sulphide ore at the extreme end of the north-east drift off adit C. Samples have been sent to San Francisco to be assayed and it is expected that the ore will be worth $100 per ton. A large slab of rock, thought to have been the end of the ore in the drift, which fell of its own weight, uncovered the deposit.

During the three months ended with October, the Seven Troughs Coalition company's revenue was $160,990. The total expense was $82,348, and profit $78,642. In four months the ore production was 1785 tons containing $186,550.

Lyon County

The superintendent of the Nevada-Douglas Copper Co. reports that the treatment of ore from the first charge of the Wedge furnaces gave an extraction of 90% by leaching. The furnaces are operating splendidly. The feeding is at the rate of about 80 tons per day. The discharge shows a perfectly roasted product. Sulphur gases from the furnaces are being used in leaching oxidized ore.

Mineral County

In the Sodaville district the development of tungsten properties occupies first place. A California firm is working the property of C. E. Noble, employing over 30 men. The old Acme mill is concentrating the ore. The whole adjacent area has been staked.

Bismuth has been found by W. R. Smith in the Cedar range, near the Copper Contact mine.

Nye County

During the week ended December 11, six companies and numerous lessees at Tonopah produced 10,114 tons of ore worth $208,012.

Silver shipped by the Belmont amounted to 149,499 oz., produced by the plants at Tonopah and Millers.

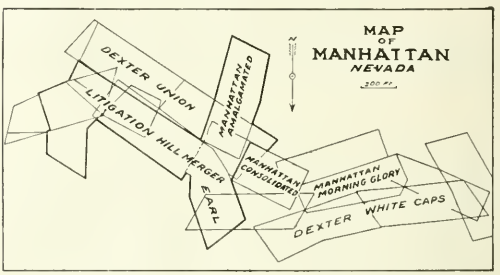
The West End will pay 5c. per share, equal to $89,424; the total to date is $536,546. Development continues good.

The Extension dispatched bullion worth $72,800, and 325 tons of concentrate valued at $11,700; this is a record shipment. The mill treats 1850 tons of ore per week. The lode from 850 to 1350 ft. continues to produce plenty of good ore.

In the suit of the Extension *v.* the West End, Judge Mark R. Averill on December 7 made an order modifying the restraining order and temporary injunction issued on July 17 against the defendent, by which the latter can resume operations in the disputed ground in order to determine what is the condition of the vein.

The Tonopah Mining Co. is preparing to develop the old California property, which adjoins the Jim Butler on the south.

At the Union Amalgamated Co.'s property at Manhattan, the preparatory work at the Earl and Merger properties necessary



before the starting of the company's mill has been about completed. At the outset it was found that the Earl's working shaft had caved from between the 75 and 150-ft. levels. This necessitated re-timbering the shaft for 75 ft., and 'mucking' the caved material from the entire shaft to the 350-ft. level. This has been slow work due to the decayed shaft timbers, track, and piping being all mixed with the waste. However, the cave proved somewhat a blessing in disguise, as the caved ground has left exposed a very promising shoot of ore in the hanging wall.

The Litigation Hill Merger shaft has been pumped out to 400 ft. This has drained the Earl and Merger workings. All is in readiness for underground work. The mill will commence on December 15. The orebodies have been sampled.

At the Big Pine a large lode has been cut in the south glory-hole.

From the Train-Chase lease on Mustang hill, 36 tons yielded $87.60 per ton by amalgamation at the War Eagle mill. A previous lot gave $100 per ton. Three shoots have been exposed in shaft-sinking.

The White Caps Mining Co. has just distributed checks making the final payment in the liquidation of the debts taken over from the old company at the time of the re-organization. It is understood that company operations are to be started shortly, the first mining work to be the sinking of the vertical shaft for another 100 feet.

NEW MEXICO

Grant County

(Special Correspondence.)—The Empire Zinc Co. is prosecuting a vigorous campaign of development at its mines at Hanover. The erection of a 125-ton daily capacity electrostatic dry concentration plant is well under way. The company's new central power-plant has been erected and is nearly ready. A number of residences for the executive staff, and good houses for general help, are being erected. This mine has been a consistent producer of zinc ore for 25 years, and from its present physical condition is apparently entering its period of greatest production. Present shipments are 1200 tons per month of high-grade zinc carbonate ore to the company's smelter at Collinsville, Oklahoma.

J. W. Bible has the Modoc mine of the Phelps Dodge Co. under lease. He has shipped 40 cars of copper-iron ore, containing from 2.5 to 5% copper, and still has considerable ore

blocked out ready for mining and shipment.

It is said that the efforts of the U. S. Copper Co. to finance its mine have been successful, and that work will be resumed on the property in the near future. The mine has produced considerable copper, and the owners claim to have shipping ore developed.

The Republic Mining & Milling Co., operating property under lease and option adjoining that of the Empire Zinc, recently shipped a carload of high-grade zinc carbonate ore, which netted nearly $40 per ton. The car was shipped to the American Metal Co., Ltd., Chanute, Kansas.

The Colorado Fuel & Iron Co. has men at work on its leased properties north of Hanover. It is reported that extensive operations will begin about January 1.

Lee and Cameron of El Paso have the Honey Comb property of the Hermoso Copper Co. under lease. They have opened good ore. Heavy ground is temporarily delaying development and ore shipment.

McKenna and Gerhart recently shipped a carload of copper ore from their property at Humbolt mountain.

Hanover, December 6.

SOUTH DAKOTA

Lawrence County

On December 27 the Homestake company will pay 65c., and an extra dividend of $1 per share. The total for this year is $8.80 per share, equal to $2,210,208. To date the payments are $167.40 per share, or $35,525,981.

TEXAS

Culberson County

(Special Correspondence.)—Good progress is being made in plans to develop on an extensive scale the large surface deposit of sulphur situated in the north-eastern part of this county, not far from the New Mexico border, by G. A. Plummer of Beaumont and a New York syndicate. Considerable preliminary work has already been done at the property, and it is announced that the work planned will cost $300,000. A direct shipping outlet for the sulphur will be obtained by the construction of a railroad to Orla or some other point on the Pecos Valley line of the Atchison, Topeka & Santa Fe; only 15 miles of track will be necessary to do this. The existence of large deposits of sulphur in this county has long been known, but this is the first time any well organized plan of developing them has been attempted.

Orla, December 2.

UTAH

Carbon County

In the Colorado School of Mines *Magazine* for December features of coal mining in Utah, principally in this county, are described by A. C. Watts of the Utah Fuel Co. The known workable beds cover 15,200 sq. miles, and contain 197,000,000,000 tons of coal. An analysis of some of the coal shows 52.73% fixed carbon, 5.45% ash, and 13,412 b.t.u. heating value. The seams are thick, and the general system of mining is by room and pillar. Aerial tramways, steel tipples, and steam turbo-generators are part of the surface equipments. First-aid is an important department, also sociological work.

Juab County

Ore containing 100 oz. silver per ton is being extracted from the Lower Mammoth 1000-ft. level. The first dividend for some years is to be paid this month.

Lessees at the Gemini have received $82,000 during the period that the mine has been opened this year.

Salt Lake County

The Karns tunnelling-machine was shown in working condition at the Maxfield mine, Big Cottonwood district, on December 5. The air pressure was 90 lb., and a hole 12-in. diameter was drilled two feet in 40 minutes. It is claimed that the cost of driving is reduced 50%, and the speed is 50% greater. The adit is 7 by 9 ft. in the clear.

At the Wasatch property the company is spending $7500 on a new pipe-line at the power-plant to increase its capacity by 500 hp. The power required by other companies in the Little Cottonwood district is increasing, hence this addition.

In the Sells mine the shoot has been opened for 140 ft., and is from 7 to 12 ft. wide, worth from $15 to $45 per ton. It is one of the best orebodies in the district. A. O. Jacobson is manager.

At 250 ft., in the Langdon fissure, the South Hecla has cut high-grade ore.

Summit County

There are more properties being worked in the Park City district than for years. The product for 11 months totals 91,477 tons, against 74,697 tons in 1914.

The Daly-Judge company is in a comfortable position, according to the general manager, George W. Lambourne. Profits distributed this year total $300,000, and the balance at the end of 1915 will be over $600,000, more than enough to pay next year's dividends. The monthly output of zinc concentrate is 600 tons. The rise in silver adds largely to the profits.

The following dividends will be paid by Utah companies during December:

Utah Apex	$ 66,000
Prince Consolidated (Nevada)	50,000
May Day	24,000
Utah Consolidated	150,000
Lower Mammoth	10,000
Silver King Consolidated	63,750
Eagle & Blue Bell	44,657
Daly-Judge	105,000
Grand Central	12,500
Mammoth	20,000
Total	$545,907

The Silver King Coalition will distribute 15c., equal $187,500, on January 1. Its total will be $13,958,000.

The total for 1915 is as under :

	Per Share.	Paid 1915.
Bingham-New Haven	$ .80	$ 227,951
Chief Consolidated	.10	88,000
Cardiff	.25	125,000
Daly-Judge	1.00	300,000
Duluth and Utah Dev.	.08	4,500
Eagle & Blue Bell	.15	135,000
Grand Central	.02	12,500
Iron Blossom	.30	300,000
Lakeview Mining	.10	46,000
Lower Mammoth	.01	10,000
May Day	.11	88,000
Mammoth	.05	20,000
*Mt. Aetna Gold	.02	5,000
Silver King Con.	.40	252,500
†Silver King Coalition	.60	750,000
Utah Consolidated	2.00	600,000
Utah-Apex	.25	126,000
Utah Copper	4.25	6,809,700
Total		$9,900,151

*Estimated.

†Inclusive payment January 1.

This is $3,000,000 more than in 1914.

CANADA

British Columbia

The net operating profit of the Standard Silver-Lead mine at Ainsworth, controlled by Spokane capital, was $112,617

during October, comparing with $88,067 in September, according to the monthly report issued by Charles Hussey, secretary, from the company's offices at Spokane. The balance on hand at October 31 was $287,358, against $224,779 at the close of September. The sale of zinc, which was started at the opening of October, accounted for $24,834. Preliminary settlement for 1485 tons of ore received during October amounted to $113,399. The company paid dividend No. 34 in October, amounting to $50,000. A similar dividend will be paid for November, and in December two disbursements of $50,000 have been declared. In the recapitulation for the month, the report shows $224,721 in the bank, and credits $94,874 for ore shipped and not settled for.

ONTARIO

The provincial Bureau of Mines reports the following production for the nine months ended September 30:

	Value.	Same period 1914.
Gold	$5,826,941	+$1,884,093
Silver	8,030,469	—2,051,760
Copper	2,024,658	+359,762
Nickel	5,369,536	+1,345,980
Iron ore	601,044	+221,126
Pig-iron	4,510,906	—1,933,307
Cobalt ore	12,472	—14,091
Cobalt metal	66,552	+66,552
Nickel metal	4,762	+4,762
Cobalt and nickel oxides, etc.	124,088	—331,403

During the six months ended September 30 the Dome output was 162,363 tons of ore averaging $4.42 per ton. The November yield was 28,600 tons averaging $5.59 per ton.

On December 2 the Hollinger paid its monthly dividend of $120,000. This makes 44% for 11 months, equal to $1,320,000, and 135% to date, or $4,050,000. The yield for the four weeks ended November 4 was 28,401 tons of $10.34 ore, and a profit of $184,769. The cost was $3.29 per ton.

On January 1 the McKinley-Darragh will pay 3%, equal to $67,431. This makes $4,471,890 to date.

MEXICO

American mining interests in Mexico are much disturbed over the recent action of the *de facto* government in increasing the tax on their properties. Of course, the increase applies to all mine holdings, irrespective of whether they are foreign or native owned, but inasmuch as Americans have large investments in the industry the burden will fall chiefly on them. The present tax is ₱60 for mining claims of 10 *pertenencias*, which is equal to 20¾ acres. Claims in excess of this acreage are taxed ₱30 for each additional 10 *pertenencias*. The new tax, which is designated to discourage small holdings, it is claimed, is graduated and is higher as the holdings increase. It fixes the tax at ₱120 for each 10 *pertenencias*, ₱270 for 240 *pertenencias*, ₱810 for 1350 *pertenencias*, and so on up. All claims in excess of 50 *pertenencias* are taxed ₱24 per *pertenencia*. Under the old law these taxes were payable in either gold, silver, or Mexican currency. Under the new law only Mexican gold or its equivalent in American money at the regular exchange basis of 2 to 1 will be accepted. The new law is to go into effect on March 1, 1916.

SONORA

The Rodriguez forces have been completely defeated, and further large battles are not expected in this state. All saloons have been closed.

Soon after the Americans left El Tigre the Rodriguez forces sacked the place, including the company's stores and houses, but the plant was not damaged.

It was expected that the Greene-Cananea mines and works would resume on December 11; also the Democrata company in the same district.

PERSONAL

ROBERT C. CANBY is visiting Berkeley.

S. F. SHAW has gone to San Antonio, Texas.

J. H. MACKENZIE is returning from New York.

WILLIAM FORSTNER has returned from Tonopah.

J. M. CALLOW was here from Salt Lake City during the week.

THOS. H. LEGGETT has returned to New York for Christmas.

F. C. BROWN, the inventor of the Pachuca agitator, is at Atlanta, Idaho.

W. H. LANAGAN has returned to San Francisco from the Cariboo district, B. C.

H. C. ENOS has just returned to Colorado after completing examinations in Utah.

HORACE M. WILSON is leaving California to return to Colombia, by way of New York.

L. H. METZGER, formerly at Goldfield, Nevada, has joined the staff of the Alaska Treadwell company at Juneau.

ALFRED TELLMAN is conducting concentration experiments for the Ridder Mining Co. in the Altai region, Siberia.

THOS. T. READ has gone to New York, where he will join the engineering staff of the New Jersey Zinc Company.

O. W. VAN LAW, second vice-president of the U. S. Smelting, Refining & Mining Co., was recently at Salt Lake City.

GEORGE H. GARREY passed through San Francisco the first of the week on his way from Colorado and Nevada to Seattle.

M. F. CHASE and W. D. MAIN severed their connections with the Mineral Point Zinc Co. on December 1. They have offices in the Marquette building, Chicago.

J. D. CONNOR, metallurgist for the South Australian government, has completed his inspection of copper-leaching plants and is returning to Australia next week *via* Vancouver.

D. D. CAIRNES, geologist in the Yukon for the Canadian government, has accepted the chair of assistant professor of geology and mineralogy in the University of British Columbia.

FRED B. CLOSE, who has been active in the development work at the White Pine Extension property, Michigan, will be superintendent in charge. WILLIAM R. BOLLEY, formerly superintendent of the Baltic mine of the Copper Range Consolidated, will be assistant superintendent.

FREDERICK G. CLAPP, managing geologist of the Associated Geological Engineers, has recently completed some explorations in Texas and has gone to Elgin, Kansas. CLYDE T. GRISWOLD of the mining department in the Carnegie Institute of Technology, and RALPH W. RICHARDS of Washington, D. C., are included in the party.

JAMES MAPES DODGE, chairman of the board of the Link-Belt Co., died at his home in Philadelphia on December 4. Mr. Dodge was one of the pioneers in the conveying and elevating systems, and his inventive genius was a conspicuous factor in its broad and successful development. Among his important inventions and improvements were those relating to the construction and manufacture of silent-chain. He was a member of many societies.

The School of Mines of the University of Idaho will offer, during January and February 1916, a short course for prospectors, miners, and millmen. The subjects treated will include prospecting, mineralogy, mining geology, mining, metallurgy, ore-dressing, concentration, and milling. There are no fees in connection with any of these courses, and instruction is free. The work is laid out especially for mature men who desire to make the most of their time during this brief period.

THE METAL MARKET

METAL PRICES.

San Francisco, December 15.

	Cents per pound.
Antimony	40
Electrolytic copper	20.75
Pig lead	5.65—5.85
Quicksilver (per flask)	$130
Spelter	20
Tin	40
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, December 15.

Antimony: market weaker; 50% product, per unit	$ 2
Antimony: 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica per ton	12
Magnesite: plastic, no iron and lime, calcined, per ton	55
Magnesite: refractory, up to 7% iron, calcined, per ton	30-35
Manganese, 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3 per unit for spot	$35—45

New York, December 10.

Antimony: per unit, $2.55.

Tungsten: 60%, $50 for deliveries in first quarter of 1916.

Manganese: Difficulty is being experienced in getting manganese ore from Brazil because of the scarcity of ships. The matter is a serious one with steel makers, in view of the lessened supply of ferro-manganese now coming from England.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 16.—The copper market is firm owing to advance in London; strength in London explains the increase in lead; the zinc market is excited, there are few buyers, but London inspires strength.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 9	56.00	Nov. 3	49.37

May	13.97	18.71	Nov.	11.75	18.88
June	13.60	19.75	Dec.	12.75	....

Exports during the week ended December 8 totaled 6,370,971 lb. valued at $1,168,633. To France went 3,547,331 lb., and 1,120,459 lb. to Russia. Imports amounted to 4,929,999 lb. worth $665,581. Chile sent 966,498 lb. and Peru 2,842,540 pounds.

In November, Braden yielded 3,684,000 lb. and Old Dominion 2,443,000 lb.; in October, Granby produced 4,124,499 pounds.

Dividends declared include $1 by Chino, 37½ and 12½c. by the Nevada Con., 50c. by Ray, and $1 and 50c. per share by Utah Copper. These four companies have cash and metal in process paid for totaling $25,000,000. The Calumet & Arizona will pay $1.25 per share.

The Copper Range Co. resumes dividends, first since October 1913, by paying $3.——Quincy is expected to produce 21,000,000 lb. this year; the monthly profit is $125,000 from 105,000 tons of ore.——The Lake Copper Co. is making a profit at last, namely, $10,000 per month.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Butte & Superior has declared its quarterly dividend of 50c. and an extra of $7.50 per share. The total for 1915 is $18. against $2.25 in 1914.

Ore prices at Joplin, Missouri, were $15 per ton lower last week, 60% product realizing from $65 to $90. The output of the region was 4232 tons blende, 220 tons calamine, and 1265 tons lead, averaging $77.70, $63.09, and $71.64 per ton, respectively. The total value was $432,362, and for 50 weeks, $24,-003,765.

LEAD

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Date.		Dec. 1	105.00

There has been a revival of antimony mining in Japan. Three mines produce 50 tons per month, while consumption of that country is 450 to 500 tons.

Eastern Metal Market

New York, December 10.

Pronounced quiet has been the feature of the past week, and it is likely that 1915 will see no more extensive buying. Consumers are well supplied, and furthermore, they are never inclined to be active purchasers at this season. The London market shows an easier trend also. Some of the smaller copper producers have lowered their asking price, while second-hands have solicited business at 19.50c., cash, or less. All the indications point to fewer new war orders, although finishing those in hand is a gigantic task. Zinc dropped over 3c. per lb. in the first 10 days of this month, but now shows a little renewed strength. Lead is in much the same position as copper; the leading interest holding up its price, while re-sellers are offering concessions. Business in tin has been confined to small lots of spot. Antimony is easier. Aluminum is quoted at 58 to 59c. for the purest grade.

Lake Superior iron ore next year will be 75c. per ton higher than the 1915 schedule. It is predicted that 1916 will see a shortage in iron ore, and the production of pig-iron may be restricted. Ore shippers are having difficulty in chartering vessels for next season. The production in pig-iron in November was at the rate of 101,244 tons per day, or 3,037,308 gross tons in the 30 days, against 3,125,491 tons in October, or 100,822 tons per day. The pace at which blast-furnaces were driven in October cannot be long maintained, as the strain is too great. Meanwhile, the prices of steel continue to soar. The situation presents various irregularities, such, for instance, as the Middle West turning to the East for steel. In the export trade all sorts of fancy prices are paid for finished or semi-finished steel. Pig-iron continues to advance. Some idea of the foreign demand for steel is afforded by the one item of 500,000 tons of shell steel which French consumers are seeking to buy in this country. Deliveries are to be made in 1916, regardless of the ending of the War. Meanwhile, domestic business continues to improve.

COPPER

The copper market has become very dull, and probably will remain so for the remainder of this year, a situation which is likely to prevail with the other metals as well. Electrolytic is lower at London, the quotation on December 10 being £97 10s. Of course, no one is surprised at the present state of the market. Heavy buying cannot go on continuously, and in the past few weeks many millions of pounds have been contracted for, some to be delivered in the second quarter of next year. Another point to be considered is the fact that quiet always prevails in the markets around the Christmas holidays. The producers have held to 19.75 to 20c., cash, New York, as they well can afford to do in view of their sold-up state, but second-hands have sought to induce buying by offering concessions and down to 19.50c., cash. Some say that 19.37½c. had been quoted. Even these prices, however, can not change the tenor of the market. The brass-mills continue to be very busy, are extending their facilities, and new enterprises are projected to enable the handling of war orders. These orders have reached flood tide, and from this time on fewer will be placed. So far this month exports have made a good showing, their total up to to-day, being 15,444 tons, or about at the rate of 1500 tons per day.

ZINC

In the first 10 days of this month the quotations for zinc declined over 3c. per pound, and demand slacked off to nothing. The New York price for spot today, December 10, stands at 15.50c., and at St. Louis about ½c. less. On Monday of this week, when 15c. was quoted there were a few large inquiries before the trade, and with the lower prices activity on the part of the galvanizers was looked for. A good part of the galvanizing trade has only bought as necessity compelled them to cover contracts on their books. Despite the inquiries referred to, the market, generally, has been one of quiet, and waiting. The London market has shown a much weaker trend, losing £7 on spot, and £9 in futures, in three days. A large amount of inconsistency is shown with regard to spelter. It is certain that buyers have found it difficult to find spot and near-by metal, yet many of the trade insist that there is plenty of the metal. Opposed to their view is the fact that the brass-mills are using the metal at the rate of about 200,000 tons per year, whereas they ordinarily consume about 80,000 tons. Then there are the large exports which from December 1 to 10 totaled 2963 tons. From this time on, however, Russian buying will be less of a factor, inasmuch as the port of Archangel will soon be closed to navigation. Consumers filled their requirements, for a time, on the recent upward movement, and it is doubtful if there will be any considerable activity this year, unless the galvanizers become active, and this they will not do unless quotations stay within what is considered reasonable. January deliveries were to be had, and some were taken, late this week, at 14.25c. St. Louis, and first quarter at 13.25c. Consumers show a disposition, however, to refrain from buying far ahead. The London market for spot was quoted on December 10 at £82, and for futures, at £69. The quotation for sheet-zinc, carload lots, f.o.b. mill, continues at 22c., subject to a discount of 8% for cash.

LEAD

The situation in lead much resembles that in copper; producers being well sold, and consumers well filled up. The leading interest has adhered to 5.25c. New York. The outside St. Louis quotations are a little easier; the leading interest quoting 5.17½c., while others ask 5.15c. The offerings at concessions, however, have not embraced any large quantities and they would soon disappear were buying to become at all brisk. Exports are restricted by the scarcity and high cost of ocean-freight space, added to which is difficulty in getting shipments to New York. Some of the railroads have declared embargoes on freight of various kinds, lead included. Thousands of cars encumber the railroad sidings. The inability to transfer freight to ships not only congests the freight-yards, but ties up the cars which are needed elsewhere. Exports this month, December 1 to 10, total 1740 tons.

TIN

The market has continued dull with practically the only business done being in small lots of spot. The quotation for prompt metal dropped to 37.25c., December 7, and today, the 10th, is 38c. As heretofore said, the market is paying the penalty of the many false reports circulated in recent weeks, which have destroyed the confidence of consumers. The quiet is expected to last until after the holidays, except for a possible spurt just before Christmas. The steamer *Indrawadi*, which was due on November 20, but which ran short of coal and put in at Bermuda, has at last arrived bringing 1100 tons, an exceptionally large shipment. Arrivals of the month, up to the 10th, totaled 2725 tons, and there was afloat on that day 5833 tons. Today, tin is cheap.

ANTIMONY

Recent arrivals have made the market easier, and spot antimony, duty paid, is now quoted at 39 to 39.50c. The demand has not been noteworthy. Both American and Chinese and Japanese grades are on the same level.

ALUMINUM

For No. 1 virgin metal, 99% pure, the quotations are 58 to 59c., and for 98 to 99%, 56 to 58c. In the general situation there is no change, and new consumers have to look long to fill their requirements.

MINING DECISIONS

Coal Lease—Rents Defined

Held, that the word 'rents' in a coal lease does not include a right-of-way charge.

Tustin *v.* Philadelphia, etc., Coal & Iron Co. (Pennsylvania), 95 Atlantic, 595. July 31, 1915.

Oil Lease—Suit for Royalties—Parties

In a suit by lessor against lessee for an accounting of royalties on oils produced, the assignee of a part of the royalty oils is a necessary party thereto, as well as all other parties whose interests are involved therein.

Gurcher *v.* South Penn. Oil Co. (West Virginia), 86 Southeastern, 560. September 28, 1915.

Rights of Surface Owners to Underlying Strata

A landowner who has conveyed the underlying coal to another is entitled to drill a well through that coal in order to obtain a water supply from the strata underneath, and if the coal-owner negligently destroys the well-casing he is liable for damages.

Pennsylvania Central Brewing Co. *v.* Lehigh Valley Coal Co. (Pennsylvania), 95 Atlantic, 471. July 3, 1915.

Coal Lease—Mistake of Law

Plaintiffs paid royalties under a coal lease for many years, and then discovered that they themselves owned part of the coal upon which they had been paying royalties to their lessor, and refused to pay further royalties under the lease until they had reimbursed themselves for this mistake. Held, that inasmuch as their mistake as to title was a mistake of law, all the facts having been in their possession at the date at which the lease was made, a court of equity could not relieve them from the consequences of their error or permit such reimbursement at the lessor's expense.

Clark *v.* Lehigh, etc., Coal Co. (Pennsylvania), 95 Atlantic, 462. July 3, 1915.

Mining Claim—Quiet Title Suit—Limitations

Plaintiff, being in continuous adverse possession of a mining claim for which defendants had applied for patent, filed an adverse claim and brought suit thereon. This suit was afterward dismissed upon an agreement by defendants to except the claim from their patent application. Plaintiff's attorney died and the defendants failed to live up to their agreement to except the claim in question from their patent application, and a receiver's receipt was issued. Plaintiff then filed a protest with the General Land Office against issuance of a patent, and commenced another suit to establish title. Held, on appeal from an order sustaining a demurrer, that the suit was a proper one; that notwithstanding the expiration of the time in which suit on a regular adverse claim could be begun, plaintiff was entitled to maintain a quiet title suit based on his own adverse possession and defendant's bad faith.

Poncia *v.* Eagle (Idaho), 152 Pacific, 208. October 9, 1915.

Pure antimony is a brilliant silver-white metal. It is brittle and soft, being slightly harder than copper. Commercial antimony is generally contaminated with small amounts of sulphur, arsenic, lead, copper, and iron, and these impurities give it a bluish tinge. The main use of antimony is in the form of alloys, the principal ones being pewter, anti-friction metal, type-metal, and hard lead.

BOOK REVIEWS

Safety in the Foundry. By Magnus W. Alexander. P. 187. Illustrated. National Founders' Association, Chicago. For sale by the Mining and Scientific Press. Price, $1.50.

Mining companies whose operations are of any considerable extent usually have foundries in connection with their machine-shops. Many accidents are possible in a foundry, such as burning and falling weights, and troubles arising from dust and steam. This is the first and only handbook of its kind to be published, and is the result of the investigations made by the National Founders' Association Committee on Safety and Sanitation during three years. The work is primarily arranged for the purpose of safe-guarding the employee and promoting his welfare, incidentally reducing compensation risks. Practical foundry-men are said to have commended the discussions therein. Some of the topics are on signs, yards, light, ventilation, cranes, trucks, ladles, crucibles, dusty work, tools, clothing, goggles, and first-aid. Mine safety departments would do well to secure a copy of this work.

Winning a Fortune. By Lewis W. Klinker. P. 477. Ill. W. B. Conkey Company.

It is not often that the Mining and Scientific Press reviews a work of fiction. This Californian story by Mr. Klinker is an exception. As the author states in his introduction, "To make money and to win a fortune quickly has a fascination for people; mining is today almost the only field left open for the realization of such an ambition. It is my purpose to combine some interesting facts with fiction and romance to make a story at once useful and entertaining. The facts, as to the names of the placer mines, are real, as is the amount of gold produced from them, which I know from personal experience in the Sierra Nevada region." Topics touched upon in the exciting account of adventures among Indians, rogues, and all kinds of frontier hardships, include crossing the plains in wagons in early days, stopping of hydraulic mining by the courts, building of the railroads, redemption of swamp-lands. In brief, the book is a thrilling tale of all kinds of exploits and experiences in the opening of a new country. Deserving of particular mention are the five illustrations of incidents in the story, drawn by the author's daughter, Miss Orpha Mae Klinker. The book is an agreeable reminder that romance and freshness of vision are not yet dead in the world.

NEW MACHINES AND DEVICES

Information based on letters and catalogues from manufacturers.

Commercial Paragraphs

STANDARD SPIRAL PIPE WORKS, Chicago, has published a circular devoted to the features and economic advantages of this company's products.

The Sheldon 'car-mover' and Dayton 'car-wrench' are two useful devices which the STEPHENS-ADAMSON MANUFACTURING Co., Aurora, Illinois, is offering.

The WAGNER ELECTRIC MANUFACTURING Co., St. Louis, Missouri, has compiled a series of small illustrated bulletins describing in detail the various products of this company.

Bulletin No. 1075-A of the ALLIS-CHALMERS MANUFACTURING Co. deals with belted alternating-current generators, types AB and AH. Many interesting details are given on their construction.

The TOLEDO SCALE Co. announces that H. O. Hem, formerly of Kansas City, has become a member of its engineering staff in the capacity of consulting engineer, and is now located in Toledo, Ohio.

Catalogue No. 2 of the CLARAGE FAN Co., Kalamazoo, Michigan, is descriptive of the products of this company, and contains a large amount of data on the construction and operation of the various types of fans manufactured by it.

The J. D. FATE Co., Plymouth, Ohio, has recently circulated an attractive folder entitled 'The Plymouth Gasoline Industrial Locomotive Cuts Haulage Costs.' The folder sets forth the many claims of superiority for this type of locomotive.

Circular A of the ST. LOUIS WELL MACHINE & TOOL Co., St. Louis, Missouri, is devoted to the well drilling and prospecting machinery manufactured by this company. The booklet is fully illustrated and contains details regarding the construction and operation of this equipment.

CLEVELAND BRONZE BRASS WORKS, Cleveland, Ohio, has for distribution an illustrated pamphlet descriptive of the 'Acimet' valves manufactured by this company. This type is acid-proof and particularly adopted to the requirements of acid manufacturers and all work requiring non-corrosive valves.

'The Terry Turbine' is the title of a new bulletin just issued by THE TERRY STEAM TURBINE Co., of Hartford, Connecticut, giving a general description of the various turbine applications, and dealing particularly with various kinds of high, low and mixed-pressure turbines. The publication is well illustrated.

The Luckle 2 Tungsten Co., operating a mill near Boulder, Colorado, has given the DENVER QUARTZ MILL & CRUSHER Co., of Denver, an order for a Denver steel crusher and a Denver quartz mill. The Denver company supplied the equipment now in use in this mill some five years ago, and this repeat order is to enable the mining company to take care of the increased quantity of ore caused by the high price of tungsten.

SAUERMAN BROS., Monadnock Block, Chicago, Illinois, has for distribution an instructive catalogue devoted to the application of the Shearer & Mayer drag-line cable-way to various types of excavation. The uses of this excavator in mining work are varied, and are particularly adapted to the working of placer deposits, recovery of tailing, and open-cut excavations. By this means large quantities are being handled at a cost which is claimed to make the drag-line excavator superior to other established methods of excavation. The catalogue is fully illustrated, and shows a wide variety of Shearer & Mayer installations.

The No. 34 Myers type dry concentrator is a new type of machine which has been developed by the SUTTON, STEELE & STEELE Co., Denver, Colorado. The new table is a modification of the older type of table manufactured by this company, is smaller, more compact, and of greater efficiency. The No. 72 machine is the larger machine, and is of much larger capacity than the No. 34, although adapted to the same class of work. A bulletin has been issued describing the construction and operation of these two machines.

The WESTERN ELECTRIC Co., New York, sends us the following: On November 18 all of the assets of the Western Electric Co. of Illinois were acquired by transfer to a company chartered under the laws of the state of New York, to be known as Western Electric Co., Inc. In the construction of the Hell Gate bridge over the East river, New York, a steel arch 1017 ft. long, the greatest in the world, the company's telephones played an important part. Owing to increased business the company has moved its Detroit headquarters to a new building of 50,000 sq. ft. floor space, and 54,000 sq. ft. in the yard.

A recent circular from E. E. WHITE, Ishpeming, Michigan, gives a few notes on the MAAS patent drill-hole compass for surveying bore-holes. Twelve of these have been rented to prominent exploration companies in the United States, Canada, and Russia, which are getting good results. The compass is placed in a thermos bottle or glass tube with hot liquid gelatine and lowered in a water-tight phosphor-bronze case, with a tube containing hydrofluoric acid. When the gelatine is cold the rods are pulled, the direction of the needle is marked on the tube which contained the acid, and direction and inclination of the hole determined from this tube in a goniometer. There is nothing to get out of order and the compass can be used by any drill foreman, the mark and etching on the tube making a permanent record of direction and inclination. The compass will survey drill-holes to a depth of 3000 ft. for both direction and inclination in the time necessary to test for inclination only. A price-list of supplies is given.

The WESTINGHOUSE ELECTRIC & MFG. Co., East Pittsburg, Pa., sends the following notes:

There have been a number of changes of personnel in the supply department.

Paul M. Lincoln, whose term as president of the American Institute of Electrical Engineers, expired July 1, 1915, and who has for a number of years been prominently identified with the engineering department of the Westinghouse company, has resigned his position with the company to devote his time to the manufacture of a meter which he has recently invented. Mr. Lincoln graduated from Ohio State University in 1892.

A new refrigerating-machine, invented by Maurice Le Blanc, who designed the well-known Le Blanc condenser, was tested before prominent engineers at East Pittsburg on October 29. A special feature of the machine is the absence of all chemicals or compressed gases, such as carbon dioxide, ammonia, or sulphur dioxide, which are generally used in connection with refrigeration. This point will readily be appreciated when the present scarcity of chemicals due to the present War is recalled. The presence of tanks of carbon dioxide under pressure is always an element of danger. The machine is made by the WESTINGHOUSE MACHINE Co.

EDITORIAL

T. A. RICKARD, Editor

NIKOLA TESLA is said to have invented a manless air-ship controlled by wireless electricity capable of going 300 miles per hour. All of us have heard of the wireless-controlled torpedo. Such inventions promise to do more to render warfare impossible than the speeches of pacifists or the argosies of perambulator-manufacturers.

CHRISTMAS in this year of grace is a satire. The world has its eyes not upon Bethlehem of Judæa but Bethlehem in Pennsylvania. The little town with its babe in the manger is replaced by a vast manufactory of death-dealing implements. Charles M. Schwab is the great protagonist of the present era. Christianity may well grieve and civilization slink away ashamed.

INCREASED cost to the amount of $21,000,000 has been incurred by the Post-Office Department during the last fiscal year on account of the War. Good results are claimed for the efforts made to stop fraudulent advertising and circularizing through the mail. Undoubtedly the Post-Office has done good work in checking predatory promotion of worthless mining schemes.

WHETHER New York becomes the money-centre of the world after the War will depend upon American investments in foreign countries. London is the great financial centre because so large a part of its investment is done abroad, for lack of adequate scope at home. The United States covers a continent still in course of development, so that much money can be used domestically to advantage.

DREDGING in California now proceeds on recognized lines, the only changes in the dredges themselves relating to the more generous use of manganese steel and a steady increase in digging capacity. For instance, the No. 15 dredge of the Yuba Consolidated Gold Mines, California, has a steel hull 155 ft. long, 65 feet in the beam, and 12 feet deep. The buckets are 100 in number, each weighing 1500 pounds, and having a capacity of 17 cubic feet. They are held by 7½-inch pins. The upper tumbler is cast solid with the shaft, which is 18 inches in diameter. This dredge digs 80 feet below the water-level and removes a bank 20 feet high above, so that its digging height is 100 feet. The cost, we understand, was $400,000 and the machine will be at work in May next.

SILVER to the amount of 3,000,000 ounces was consumed by the Eastman Kodak Company during the year 1915. This suggests one of the items of consumption that helps the honest miner to get a price on his ore. The silver used by the camera is lost for good, that is, it is permanently diverted from the market. Moreover the growing cinematograph industry must consume several more million ounces of silver, so that when the miner on a holiday comes from camp to town he will be logical in patronizing the 'movie.' The one thing to be deprecated is the bestowal of iron crosses; as miners, we ought to insist on silver badges—the heavier the better—being used as the insignia of virile manhood.

OUR Melbourne correspondent sends one of his occasional but always interesting letters. He writes concerning the efforts made by the Commonwealth government to control the metal trade in the interest of the Australian people. While some of the steps may be prompted by hostile feeling against the present enemies of the British Empire, it is apparent that the underlying idea is to rid the mining industry of the tight hold of the German metal-merchants and to encourage the establishment of domestic manufacture. We have written several times in these columns concerning the non-national or international coterie that has a dangerous grasp of the metal business at London, New York, and Melbourne. Recognizing the danger of such control, we have taken pains to obtain metal quotations from an independent source. Anybody in charge of the sale of metals from our Western mines who does not avail himself of the protection afforded by the quotations published in this paper is unwise, to put it mildly.

AT the recent meeting of the San Francisco section of the American Institute of Mining Engineers the subject of flotation had been selected for discussion. Mr. E. H. Nutter, the local representative of Minerals Separation, Ltd., was invited to open the proceedings with an outline of the physico-chemical principles underlying the phenomena of flotation, but, for political reasons, he was unable to accept the invitation. Whereupon Mr. Edward C. Franklin, professor of organic chemistry in Stanford University, was invited to start the ball. He accepted, but, at the last moment, was prevented, by illness, from coming. Fortunately Mr. Robert C. Canby had come to the meeting as a guest, so he was persuaded by the chairman, Mr. G. H. Clevenger, to make the introductory remarks. Thus, by the irony of fate, one of the principal experts in behalf of the Miami Copper Company in the recent litigation took the place of the Minerals Separation representative. In consequence, we heard more about 793,808 than about 835,120.

and were more impressed by the efficacy of air than of agitation. It was a pity that both sides of the controversy were not adequately presented. We hope that Mr. Nutter may enlighten us when next we meet; or must we conclude that obfuscation rather than illumination is the desideratum of the gentlemen whose main office is at 62 London Wall?

Electrolytic Zinc

Mr. John D. Ryan, president of the Anaconda Copper Company, has confirmed recent rumors that a large electrolytic zinc plant is to be erected at Great Falls. On December 13 ground for the new works was broken, Mr. Ryan holding the plow and Mr. Ben B. Thayer driving the team while the first furrow was upturned, preparatory to clearing a site for the foundations. The new plant is to have a capacity of 70,000,000 pounds of spelter per annum and is to be completed by September next at a cost of $2,000,000. The decision to make this metallurgical departure is the sequel to a series of careful working-tests conducted under Mr. E. P. Mathewson's direction at the Washoe works. Of course, the choice of Great Falls as the site for the electrolytic plant is due to the fact that cheap electric power, of which 30,000 horse-power will be required, is available there, from the Missouri river. The experimental plant at Anaconda began operations in October, it has a capacity of 10 tons daily, but the actual output of zinc has been only three or four tons per day owing to the lack of an adequate concentrator for zinc ores. We understand that the refinery will be enlarged immediately to 25 tons capacity. Meanwhile another interesting step will be taken, namely, the building of a concentrator of 2000 tons daily capacity, using the Minerals Separation process of flotation, which will then supply zinc concentrate for both the zinc refinery at Anaconda and the one at Great Falls. As regards the treatment of the zinc concentrate, the process is a modification of the old sulphate roast as worked out by Mr. Frederick Laist and his assistant, Mr. F. F. Frick. The ore is first oxidized by a gentle roasting and is then leached with dilute sulphuric acid. Impurities in the solution are precipitated, the iron by means of limestone, the copper and cadmium by means of zinc. The main thing is to get a pure solution of zinc sulphate; this is then electrolized, using insoluble lead for anodes and either aluminum for cathodes or starting-sheets of zinc that have been deposited on aluminum sheets and then stripped. After the zinc has been removed from the electrolytic tanks it is melted in a small reverberatory furnace in lots of a few tons and ladled into bars of 50 pounds each.

Electrolytic zinc, being practically free from impurities, is extremely tough and particularly suited for the manufacture of the highest quality of brass, such as is used in munitions. In our issue of January 2, 1915, we published a description of another electrolytic method of zinc precipitation, as conducted at Palo Alto, California, by means of the Carl Hering patent, the idea of which is to employ an electrode able to combine with, and thereby remove, the impurities in the zinc sulphate solution. This is supplemented by the purification of the zinc sulphate solution by means of evaporation and crystallization. The plant at Palo Alto has treated small lots of baghouse fume from the Shasta county smelters and has produced some spelter of unexceptionable purity. However, the thickness of zinc precipitated has been so small as to interfere with practical success. Other experiments have been in progress in Shasta county, by the Bully Hill company, on lines similar to those of the process now successfully developed in Montana, save that the leaching is done with the acid electrolyte, so that the amount of sulphuric acid remains practically constant in the cycle of operations. Here also the experimental work has progressed to the point where the construction of a large plant is justifiable. We are informed that such a plant is to be erected within the next six months. This will lead to the resumption of smelting at Balaklala and Bully Hill. But the fact remains that the problem was solved first at Anaconda. This is an event of supreme metallurgical importance, for it marks the doom of the old retort furnace and the clumsy distillation methods hitherto in vogue in Europe and America. Combined with the successful concentration of the by-product zinc in copper, lead, and precious-metal ores by means of the flotation process, this radical change in the metallurgy of zinc will have far-reaching effects. The precipitation of the zinc from an ordinary complex ore yields a concentrated residue readily amenable to ordinary lead or copper smelting practice. Instead of the minor zinc content being the excuse for the exaction of a heavy penalty by the smelter, it will be a saleable by-product. This beneficiation of the zinc hitherto worse than valueless will cause a cheapening of the metal and a further extension of its use in the arts, especially in the galvanized iron industry.

Exit Villa!

On December 18 General Villa sent an announcement from his headquarters at Chihuahua that he had decided "to leave the Mexican field of war and temporarily retire to a foreign country." In short, he gave up the contest against the Carranza government and started to go into safe exile either in California or Cuba. Incidentally, the newspaper scribe who prepared Villa's valedictory was enabled to introduce some amusing hits at the expense of the First Chief of the Constitutionalist party, now President *de facto;* but for these sallies we have no space. The main point is that the military chiefs of the Villa *revoltosos* begged him to quit for his own sake and to make it easier for them to surrender to Carranza. Two days later it was reported from Washington that Villa would receive asylum as a political refugee in case he entered the United States. Obviously the State Department is only too pleased to see him eliminated from the Mexican tangle, for the event is bound to prove a big step toward the pacification of the country.

We hope that Villa will disappear. It would be pleasant to forget him. Just now we recall Kipling's maxim

that "the more we remember the less we forget." More Indian than Spanish, Doroteo Arango—to give his real name—was a murderer at 14 and a butcher's assistant soon after, becoming a brigand and a chief of bandits in the mountains of Chihuahua while still a mere youth. He is now 47. Early in his career he became known as Pancho Villa. During the Madero revolution he emerged from the mountains and developed into a successful soldier after the Mexican fashion. Thereupon his name became General Francisco Villa. A fearless man and a rigid disciplinarian, he rose under Carranza to the chief military command and retained it until mistrust caused a division, and then a feud, with his superior. An unlettered ruffian, he was wholly unfit for high political office, yet at one time it looked as if he were about to win President Wilson's support. Fortunately the logic of events prevented any such blunder. To have strained at Huerta and swallowed Villa would have been a historic miscomputation.

The popularity of Villa was due largely to his distribution of spoils among the lesser bandits. Property, when confiscated, was divided among his relatives and henchmen. The great haciendas in the North were parceled among his various friends. This free-handed scattering of the spoils of civil war was the secret of his domination. That and his courage. In his farewell statement he refers to his "financial situation" and asserts that he is taking with him "an amount of money equal to a Mexican general's salary for two year's service. Not one cent more." We do not doubt the accuracy of this statement, for we have an idea of what a Mexican general's salary ought to be in the Mexican general's own opinion. We presume that it is a good deal like a predatory promoter's notion of what "is coming to him." When marauding he knew no qualms. Rapine and murder camped in his tent; blackmail rode in front of his squadrons. To support his army he despoiled the countryside, driving cattle across the Rio Grande, shipping cotton from Tampico, and selling millions of bushels of the corn needed to keep the non-combatant population from starvation. By such means he obtained money; also by exacting ransom, and by printing paper money. This rampant brutishness was relieved by one good quality, physical courage, the first requisite of a soldier, but not so uncommon as to deserve special consideration.

No false sentiment should cloak the fact that Mexico had no chance of law and order so long as Villa was in command of an army. With his exit we see a good prospect of better days. At present, out of a total population of 15,000,000, barely 100,000 are under arms, while 200,000 are in some sort of sympathy with the belligerent parties. The refugees in exile number fully 600,000; and these, while not among the most virile element of Mexico, include many of the most intelligent. Out of the entire population we may set aside 12,000,000 Indians and 2,000,000 of either Spanish or mixed blood as non-combatants. Only a mere fraction of the Mexican people is now on the war-path; therefore the new government, backed by the United States, ought to be able to establish itself firmly at an early date. By aid of an embargo on the export of munitions from this country to any rebel forces and by help of financial patronage from Washington, it ought to be practicable for the Carranza administration to stamp out Zapata and the remaining political incendiaries. Already signs of returning confidence are apparent, mines are being re-opened here and there, and plans are being prepared for the active resumption of mining activity, especially in the North. There is $700,000,000 of American capital invested in Mexican mines and there are hundreds of professional careers linked to that great mineral region. We hope, and believe, that for the money and the men interested in peaceful industry in Mexico there is coming a renewal of opportunity.

Concerning A Clam

The business of a newspaper office is to collect and distribute information. This is especially the case in the office of a technical journal to which comes a constant stream of inquiries on all sorts of subjects, such as the probable demand for metallic molybdenum, the influence of lime on the selling price of baryta, or the best method of working a deposit of nickeliferous iron. Any information obtained by the editor is regarded as valuable in so far as it can be given to someone who needs it. A newspaper is the spendthrift of knowledge. It saves nothing and gives all. The practising engineer, on the other hand, regards knowledge from a different point of view. For him knowledge may be capital. The inquiry from the man who has molybdenum for sale leads the engineer to look for the buyer and to see if he cannot make a fee either by showing the molybdenite miner how to open his mine and how to concentrate the ore or to find capital for a profitable venture. Thus he seeks to be of service to seller, buyer, and the public at large. For if he who makes two blades of grass grow where only one grew before deserves praise, more is he of service who adds to the world's industrial activities and metallic resources another mine. A college professor occupies a middle ground between the practising mining engineer, who is always willing to exchange his knowledge for a fee, and the editor, who is anxious to give his knowledge away in exchange for a reading public. The professor is paid by his college not only for the instruction that he gives his pupils but also to work for truth and righteousness—sometimes within the limits set by the governing board. In this general search for knowledge a situation often arises when a word from the man who knows, be he editor, engineer, or professor, may have important practical consequences. For the editor, there is no problem if, for example, an inquirer asks his advice about spending $10,000 in a new process for extracting gold from a rock in which no gold is found by assay, but which is said, by a new application of radium combined with X-rays and the gyroscope to contain nascent metal. He will advise the gold-seeker to abandon the quest. The engineer would doubtless express his willingness to look

into the problem for a fee; and if no fee were in sight, he would also state plainly that the process was a fraud. As a rule, college professors are equally ready to give free information, but some sit with tightly-folded arms hugging their little bag of knowledge as if in deadly fear that it may escape through other than the normal channels of lectures or writings. Some indeed carry this feeling so far that one of them when asked by a recent graduate to criticize a proposed publication in the professor's specialty, refused, although he was aware that the ex-student's theories were false and likely to mislead the reader. Frankly, we cannot understand this professorial attitude. The editor feels it a duty to publish at once the denunciation of an error, so that his public may be benefitted, and it is a mystery to him why the professor should not be equally willing to work in the cause of truth. Fortunately such cases are rare—so rare as to be astonishing when found. We discuss the subject in order to prevent the one instance of which we are aware from becoming a precedent. Needless to say, it does not concern us or any personal friend. We discuss the matter in a spirit of detachment.

The Story of a Career

In this issue we publish an interview with that distinguished mining engineer, Mr. Hennen Jennings. For the length of this interview we offer no apology. Those who read it will realize that none is necessary. "The proper study of mankind is man." Nothing can exceed in human interest the story of an honorable career when told by an engineer to engineers. The contemporaries of the man interviewed will be keen to read what he has to say about his own doings and quick to appreciate his friendly mention of themselves. We find, on counting, that Mr. Jennings makes mention of 130 persons with whom he has been, at various times, brought in contact. Moreover, the younger men, to whom the subject of the interview is known only as an outstanding personality, will discover in the recital of his experience a wealth of suggestion and stimulus.

We find much on which friendly comment could be made. Mr. Jennings is one of hundreds to whom Shaler was a friend in trouble and a guide in success. Surely the gift of friendship that Shaler gave to so many young men during his long professorship at Harvard will continue to exercise its vibrant impression long after his lectures and poems are forgotten. But Shaler was only one of many notable personalities at the Cambridge of forty years ago. The magnetic touch of such men might well be felt for many years after the Harvard graduate had gone forth into the arena of life. Of course, New Almaden and El Callao afforded excellent training for the bigger work of Mr. Jennings in South Africa. The account of the introduction of the cyanide process on the Rand is particularly interesting. Evidently the discovery of zinc shaving as a precipitant for the gold was the first step in the practical success of the process. The next big event was the deep-level exploration of the banket seams, for which Mr. J. S. Curtis is given proper credit. He will be known best to Western miners as the author of the Eureka monograph. As will be seen, we ventured to put a delicate interrogatory in regard to the persistence of ore in depth and received a characteristically circumspect reply; yet, reading between the lines, it can be inferred safely that Mr. Jennings recognizes the inescapable reality, for, among other hints, he makes reference to the fact that even Methuselah found, as Voltaire said, that "*la vie, c'est une maladie mortelle.*" Perhaps Mr. Jennings had in mind an editorial that we wrote, in another place, 12 years ago, when the South African promoters, and engineers, were talking a little too exuberantly about sinking shafts to a depth of 8000 feet, to cut the Main Reef series at 18,000 feet on the dip. Well, 'Even Methuselah died' is not an unfitting epitaph on those irideseent dreams of unwearying persistence. The son of Enoch shows signs of 'handing in his checks.' However, let "the dead past bury its dead." Another and easier question to answer concerned the international components of the engineering fraternity on the Rand and the harmonious relations subsisting between them. We can understand readily that Mr. Jennings himself would ignore provincialisms of any kind, for we know how, in return, he won the personal regard of the English engineers, as is proved by his election twice to the presidency of the Institution of Mining and Metallurgy—perhaps the most signal honor out of many that he has won.

Indeed, it is a fine profession that can be typified by such a man as this. From a little town on the Ohio river to the capitals of Europe and America he followed his destiny, serving his apprenticeship in California, gathering basic experience in Venezuela, and applying a rare sagacity amid the delirious developments of the greatest goldfield in the world, the Witwatersrand, that 'white waters range' in the Transvaal where the biggest natural depository of precious metal in human history was uncovered by the mining engineer. Throughout the maze of circumstance we see the directing force of a strong character. Not quick to make decisions, not flashy in the expression of his mind, lacking the intuitions of nimbler brains, Mr. Jennings won respect and esteem for his poise, for soundness of judgment, and a rare balance of mind that proved of inestimable value to his famous clients at a time when they were developing the resources of a continent and engaging themselves in speculations of gigantic dimensions. If Alfred Beit was the piston, and Julius Wernher the fly-wheel of that notable partnership, it is clear that Hennen Jennings was the governor that regulated the safe motions of a great financial and industrial mechanism. For ourselves, we like best of all his own summary of his career and the discriminating appraisal of a fine achievement. To his friends, the last paragraph will seem characteristically modest; to the younger men it conveys the clear lesson that not much of enduring value can be done without the gift of co-operation, the ability to enlist the sympathetic help of others, the unselfishness to give them credit for such help, and that consistent capacity for taking pains that surmounts all obstacles.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Safety in Mining

The Editor:

Sir—Referring to the article which appeared in your issue of August 7, 1915, on page 201, entitled 'Safety in Mining,' I beg to draw your attention to the quotation of an opinion which is attributed to me, in connection with the use of strap-irons as opposed to T-rails in incline-shafts. I do not remember ever having made the statement that "the best installation for a rope-hoist in an incline-shaft consisted of longitudinal stringers equipped with heavy strap-irons." The incline shafts of the East Rand Proprietary mines were equipped with 60-lb. rails, and not with strap-irons.

FRED HELLMANN.

Chuquicamata, Chile, October 17.

Mining Accidents

The Editor:

Sir—The letter published in your issue of December 4, entitled 'Mining Accidents,' contains a thought concerning Harry L. Day that is certainly not warranted by fact. It is true that at many properties work is carried on without proper consideration of the safety of employees. I have worked in some of these and have quit at times because of the danger. I have also worked as a laborer in Mr. Day's mine and know from personal experience that your correspondent's reference to him carries an unjust suggestion. I do not know Mr. Day, but am satisfied that if the care and well-being of employees had everywhere received the attention that has evidently been given it by him, the Safety First movement at mines would not have required the prominence that it has received lately.

PAUL M. PAINE.

Taft, California, December 7.

The Editor:

Sir—In reference to your article of November 13 regarding mine accidents and their causes. There is a statement by J. W. D. that 99 out of every 100 times the management is to blame. In regard to carrying powder, caps, and fuse up or down ladders, he asks have you ever tried it yourself. Yes. I have been mining for over thirty years, and I never saw or heard of a man killed from carrying powder, caps, and fuse up or down ladders. I would like to ask Mr. J. W. D. if he thinks it would be good management to have powder magazines on every floor in a stope that is many sets high and wide and endangering the lives of from 50 to 100 miners. J. W. D. said if the manager would go into the mines and work as a miner he would be able to prevent some of the accidents. As a rule the manager is not a good hammer-man but he is a good business man and he has his superintendent, foreman, and shift-bosses, and they as a rule are all practical miners. They are the men that are responsible for the miner. Over 60% of all accidents are due to the carelessness of the miner and not the mine manager.

P. J. DONNELLY.

Eureka, Utah, November 17.

[The discussion on this subject is now closed.—EDITOR.]

Moving Machinery

The Editor:

Sir—Responding to the letter of Mr. Storms in your issue of November 20, I offer the following note:

The local authorities own a pile-driving outfit consisting of a single-drum donkey-engine and a one-ton pile-driver hammer. When not in use on county work, this outfit is subject to loan to anyone in the county, with the understanding that the user has to get the outfit from where the last party left it.

We required the outfit to do some pile-driving. A bridge-contractor had left the equipment in a river-bed which was comparatively dry, but with a very soft bottom at the time we went for the outfit, taking with us several jack-screws, two sets of rope-blocks, some picks and shovels.

We picked up plenty of blocking near the site of the bridge, jacked the donkey-engine up high enough to run the wagon under it, then letting it down on the wagon-frame we found that it was necessary to build a temporary corduroy road to keep the loaded wagon from sinking in the soft river-bed.

This being too soft for the horses to do efficient work, we used one set of rope-falls, pulled by a team, to pull the loaded wagon up the bank and the second set of falls was secured to a stump and used to keep the donkey-engine from tipping over by hauling in the slack as the load was moved up the river-bank and onto the road, which has just been completed.

This road was too soft to suit the horses, so we used the rope-falls, secured to convenient stumps, to move the load along, keeping the horses on the solid ground alongside the new road. After going a short distance we found a place in the road that had been filled with old

trees and later burned, so we almost lost our load by upsetting. The second set of rope-falls was again used to keep the outfit on the wagon while it was jacked up and a small amount of corduroy road built under the wagon.

This concluded our mishaps. After going about one-quarter of a mile, we finally reached the old road where four horses handled the five-ton load with ease. By the time we reached our destination, a distance of two miles from the starting point, the work had required nine hours.

E. P. Dudley.

Kellogg, Idaho, November 23.

Flotation of Gold Ores

The Editor:

Sir—Mr. A. E. Drucker, well known for his work in cyanidation, in a letter appearing in your issue of November 20, made some very pertinent remarks in regard to flotation, more particularly concerning its application to gold and silver ores. His view is that of a metallurgist rather than of the man interested in the introduction of flotation. There is, as Mr. Drucker points out, a place in nearly every gold and silver mill for a flotation plant, and from the work that I have done so far, I have come to the same conclusion, namely, that flotation will be used in connection with water concentration, and that its best place in a gold and silver mill is in the treatment of the slime.

I think that in the future a common method for the treatment of gold and silver ore will be concentration by water and the treatment of the resulting sand by cyanide, with the use of flotation for the slime. A scheme like this could be adopted in many cases, thus obviating the necessity for fine grinding. The removal of the pyrite from the sand would allow quick treatment by cyanidation of the sand and the flotation of the slime, which would do away with the most expensive part of the cyanide plant, namely, the slime annex. However, the constantly recurring questions would be: what to do with the flotation concentrate? Considerable work is now being done in our laboratory to obtain a flotation concentrate low in insolubles. The average amount of insolubles is about 30%. I am now carrying out some tests to reduce these insolubles to a minimum, because if the concentrate is to be handled or shipped, it should contain the lowest possible percentage of insolubles. Flotation is now on the map and will be appearing constantly in the flow-sheets of the future.

Chas. Butters.

San Francisco, December 13.

Tuolumne

The Editor:

Sir—In your issue of December 11, in an editorial commenting on mining conditions in Tuolumne county, I notice an error which I wish you would correct.

You state that "the old Rawhide mine, near Jamestown, formerly owned by Capt. W. A. Nevills, is being unwatered and re-opened by the Pittsburg-Silver Peak company. The mine was examined and re-opened on the recommendation of Mr. Duncan MacVichie."

The Pittsburg-Silver Peak Gold Mining Co. at present has an option to purchase the Rawhide mine. We are now starting the work of unwatering. There has as yet been no examination made, and will not be until the water is out of the property. Mr. Duncan MacVichie had nothing whatever to do with the acquiring of this property by the Pittsburg company. Whatever examination has been made has been carried on exclusively by the staff of this company.

W. A. Bradley, General Manager.

Blair, Nevada, December 16.

Misuse of Technical Data

The Editor:

Sir—Recently my attention was called to a certain advertisement and an inquiry was made regarding it. The advertisement was not unlike other pamphlets of its kind, but as a whole more bold in general statements. It took advantage of some recently published notes on assaying as an argument in favor of certain so-called secret processes that the writers of the paper in question were fostering. Apparently the pamphlet was not meant for an engineer, rather for those who were confident that they had something in their ores but did not know what it was, or possibly would not believe the reports of reliable men. The material was without question a flagrant misuse of technical information: information that had an element of discussive features; it was something new and differed to a certain extent from other published papers on the same subject; for this reason, no doubt, it was singled out for their purpose.

I think that in the experience of every engineer such matters are brought to his attention at one time or another, and it is my opinion that they will second me when I say that the only remedy for an evil such as this is through the medium of the press. Unfortunately the technical papers that expose such matters reach those who already know the tricks practised.

The misuse of technical information is quite common, but unfortunately those misusing it are themselves technical men and therefore clever enough to employ it without casting suspicion upon themselves. The misuse of information pertaining to new metallurgical processes is the more common. I have noted several advertisements claiming that the extraction of a certain element can be made. Upon investigation it was found that in most instances a recently published set of notes on experiments or tests was being used as a basis: this in itself is not harmful; but when the published notes are for a certain ore and probably a refractory one, they can in but few instances be considered as applying to a class containing that particular element.

Frank A. Crampton.

Los Angeles, December 9.

Flotation—A Paradox

By DUDLEY H. NORRIS

Flotation is a paradox. In a flowing mixture of finely pulverized ore and water it causes the heavy metallic sulphides to float to the surface, where they are collected for further metallurgical treatment, while the light barren gangue sinks to the bottom and is run into the tailing-pond.

This apparent reversal of the attraction of gravitation is due to the introduction into the flowing mixture of a small quantity of oil or other emollient in such a manner that every particle of the ore, whether metallic, or gangue, is brought into contact with the oil, whereupon there is what seems a selective action between the oil and the metallic particles such that these become coated with the oil, whereas there is no such action of the oil upon the gangue. Under proper conditions, at or about the same time that this oil coating of the metallic particles takes place, there may be caused to appear in the flowing mixture bubbles of air. These attach themselves to the oil-coated metallic particles and stick to them with more or less tenacity, making a new entity consisting of metallic particle, oil-coating and air-bubble. The specific gravity of this entity is less than that of the water of the flowing mixture; thereupon, because of the attraction of gravitation, and not in spite of it, the heavy metallic sulphides float to the surface and the comparatively light gangue sinks to the bottom, neither oil nor bubbles having any tendency to attach themselves to the barren gangue.

My interest in flotation arose from the accumulation at my mine, the Magistral, at Zacatecas, Mexico, of a couple of hundred thousand tons of chalcopyrite ore of low grade which I had tried unsuccessfully to treat by water concentration. I came to San Francisco in February 1905 and went to London in June 1906, to investigate the two Elmore processes. I sent some of my ore to London and the tests showed a saving of 90% or more by the vacuum process. I set up an Elmore laboratory plant at the Magistral mine, 9000 ft. above sea-level, but got no satisfactory results—I judged that the altitude acted as a partial vacuum and that there was no air left in solution in the water. I then led a small pipe from the air-compressor and, tying a folded pocket-handkerchief over the end of the pipe, fed compressed air into the flowing mixture through 16 thicknesses of fine linen, 150 threads to the inch. I found that with a light pressure of air the bubbles coalesced on coming through the fabric and when released and started on their upward journey were of a uniform size, about that of a marrow-fat pea. With greater pressure the size of the bubbles was reduced, but the action of the air was so violent that the mixture was like a boiling geyser and everything, ore and gangue alike, was brought to the surface. Thereafter my flotation experiments were suspended until one day in a Pullman car on the Mexican Central railroad I drew some water into the hand wash-basin and I noticed that it was as white as milk, but presently became just ordinary transparent water. I saw at once that this was due to an artificial aeration of the water in the tank under the car, and when the train stopped, I read from the gauge that the pressure in the tank was 11 atmospheres. That seemed to be a solution of the problem of the lack of air in the water of the Elmore process; so I patented the method, together with the apparatus for utilizing the same.

It is not proposed here to discuss any theories of flotation, surface tension, ions or static or electric conditions or to explain phenomena, of which we at least know a little, in terms of something of which we know less. Instead of that, a classification is suggested, homely and commonplace in its terms, but which will impress upon anyone the exact limitations of each kind of flotation.

The oldest flotation is that including Everson, Froment, and others, and the Minerals Separation. It produces an "agitation to form a froth" and is exactly duplicated by the activity of the cook with a Dover egg-beater stirring what she is apt to call an "egg omelette."

Then there are the Australian processes known as the De Bavay and the Delprat, where an acid acts upon an alkaline carbonate and releases the carbonic acid gas, which action is duplicated in common life by the efficient Seidlitz powder.

Then there is the Elmore, which gets from ordinary water the air that the goldfish in the aquarium gets, and no more.

Then there are the Callow and the Towne processes, where air is forced through a porous medium, as above described; and, finally, the Norris process, which utilizes the air dissolved in water under pressure, as seen in the Pullman car or in the water-service at many places on the eastern shore of San Francisco Bay.

I believed that I had discovered a basic principle in flotation, and in September 1906 I applied for U. S. patents on the method and on the apparatus for using the Pullman bubbles in flotation; later I took out patents in ten foreign countries on the same basis. Continuing my metallurgical investigations in the summer of 1907, I went to nearly all the principal copper-concentrating mills in Colorado, Utah, and Arizona, and to Cananea. I saw all the stars of the first magnitude in the copper metallurgical firmament, but they shed no light on flotation. In fact, I was asked how the word was spelled. The net result was that I went back to Zacatecas and later built the Magistral smelter.*

*See 'The Copper Handbook,' 1912, page 545.

About this time I received word from my patent attorneys that I was opposed in the London patent-office by the Minerals Separation; but I instructed them not to appear and the case went on without me, as will be seen by the decision in the case where it is cited that "At the hearing Mr. Ballantyne appeared for the opponents; the applicant was not represented." Notwithstanding the fact that the opposition had things all their own way, the London patent-office over-ruled the opposition and decided in favor of issuing my patent, and when the Minerals Separation appealed to the law-officer the decision was affirmed, on February 24, 1910, and the British patent duly issued to me.

In the recent case of Minerals Separation against Miami, counsel for plaintiff said that the defendant interpreted the older patents, not in the light of the state of the art at the time the respective patent was applied for, but in the light of later developments. It so happens that a reference to the decision in Minerals Separation *v.* Norris, before the British patent authorities, shows that the Minerals Separation is now doing that very thing.

My British application was dated June 27, 1907, and was opposed by the Minerals Separation on the grounds of prior British patents, as follows:

No. 12,776	A.D. 1905—Froment
No. 29,283	1904—Elmore
No. 7,803	1905—Sulman
No. 26,712	1905—Sulman
No. 13,268	1907—Hoover

These include the British patents corresponding to some of the American patents on the basis of which the Minerals Separation sued Hyde and Miami in the United States courts, and the suits are now pending. The case in the British patent-office was decided, and the decision bears date, March 15, 1909. Consequently the position of the Minerals Separation as to the basis of their patent rights as stated in the case against me, between June 27, 1907, and March 15, 1909, is the true statement of their own idea of their rights and position and not that set up in the later cases some years after, and in the light of the more mature experience which is protested by Minerals Separation itself when used by the Miami company.

Here is the Minerals Separation position in the case against Norris, as appears in the decision, which says that Mr. Ballantyne relied mainly on the Sulman and Hoover patents. He contended that the underlying idea of the various processes is asserted in Claim No. 1 of the Sulman patent, that is, introducing by some means or other air under pressure into pulp containing oil and water and then allowing the pulp to come into a vessel which is open at the top to the atmosphere.

Claim No. 1 of the American Sulman patent "consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of 1% on the ore) agitating the mixture until the oil-coated mineral matter forms into a froth and separating the froth from the remainder by flotation." There is no hint in Mr. Ballantyne's presentation of his case before the London patent-office that he or his client, the Minerals Separation, placed any importance upon the little phrase in parenthesis (amounting to a fraction of 1% on the ore) and it can hardly be imagined that any court would permit, at this late day, a substitution of another idea for what Mr. Ballantyne claimed, in the case against Norris, to be the underlying idea of the various processes.

The decision, in my favor, contained these words: "It appears to me therefore, that the applicant is entitled to a patent for his invention****I decide therefore to seal a patent on the application***" The Minerals Separation appealed, but the decision was affirmed and the patent issued February 24, 1910. The Federal Circuit Court of Appeals, on appeal, decided the Hyde case against the Minerals Separation, in these words:

"We hold that to sustain the appellee's patent would be to give to the owners thereof a monopoly of that which others had discovered. What they claim to be the new and useful feature of their invention, as stated by their counsel, is agitating the mixture to cause the oily-coated mineral to form a froth. As we have seen, that feature was clearly anticipated by the prior art, and when the elements of the appellee's claims are read one by one, it will be found that each step in their process is fully described in more than one of the patents of the prior art, with the single exception of the reduced quantity of oil which they use."

The judgment of the court below was reversed by the Circuit Court of Appeals and a motion for a re-hearing was denied. Then the Minerals Separation applied to the U. S. Supreme Court for a writ of certiorari, which was granted, and the case is now before that court. The Minerals Separation advertised that the Supreme Court had granted their petition, without going into details as to just what the petition was. As a matter of fact, the granting of a writ of certiorari by the Supreme Court is in no sense a decision on the merits of the case.

Prior to 1891 an appeal to the Supreme Court from a Circuit Court was a matter of course, if the sum involved reached $1000, the result being a crowded calendar, years behind. In 1891 the Judiciary Act abolished the Circuit Courts, merging their functions in the District Courts, and creating the Circuit Courts of Appeals with final jurisdiction in many classes of cases, including patents. The Act provided for a writ of certiorari in cases where the judgment of the Circuit Court of Appeals is final and the rules of the Supreme Court say that the writ will issue where cases of great gravity or importance are involved or where two different Circuit Courts of Appeals have rendered conflicting decisions.

The proceedings on the application are very technical. A petition must be presented setting forth the facts of the case together with the reasons for the writ. Two weeks notice, or west of the Rocky Mountains, three weeks, to the adversary; and no petition will be granted within a fixed time before the end of the term. With the petition must be filed a certified copy of the papers

on which the court below acted and 30 copies uncertified. No oral argument is allowed. As Chief Justice Fuller expressed it: "The inquiry upon the application is whether the matter is of sufficient importance in itself and sufficiently open to controversy to justify the writ."

At the October term of 1914, at which the petition for the Minerals Separation writ was granted, there were 45 applications for writs of certiorari, of which 11 were granted and 34 denied. In the reports no reason is given for the Court's action in deciding petitions for certiorari; but it is extremely probable that a certain number of the applications were denied because the technical requirements of the rules were not observed. That is about the gist of the present state of the Hyde case. There has been no pardon nor commutation nor reversal, but merely a stay of execution.

The Minerals Separation also advertised that they had 36 patents on flotation, suggesting that their collection includes about all the flotation patents that have any real value. Unfortunately for this view, there is a letter in existence written by the Minerals Separation which says: "It is our custom to add flotation patents to our collection if they can be obtained reasonably whether they are of any immediate importance to us or not." That being their custom and the decision of the Circuit Court of Appeals being so strongly against them, the inference is irresistible that however little these waifs and strays of patents were bought for, they were not worth it.

One can understand the keen regret on the part of the Minerals Separation that their Froment process had not been patented in this country, but only in Italy and England. They started with the Cattermole process, which was not a success, and acquired the Froment afterward. The Cattermole, using 4 to 6% of oil, was an improvement on the Elmore, which used more. They acquired the Froment, which was a bubble process as against the processes using only oil, and then began a new series of American applications for patents. The attempts of the Minerals Separation to get a foothold in this country for their processes of flotation by "agitation to form a froth" begin with 835,120 Sulman *et al.*, dated November 6, 1906. This contained the agitation-to-form-a-froth idea but it is crudely worked out. Next came:

953,746. Hoover, April 5, 1910, with three beaters in an agitation-vessel; but this claims only one in patent for apparatus. Next came

955,012. Sulman, April 12, 1910, for process corresponding to Hoover's apparatus. Then

955,857. Hoover, December 27, 1910, claims mixing-vessel, an agitator therein, spitzkasten; also, a secondary mixing-vessel. Then

1,064,209. Hebbard, June 10, 1913. Claim 1. Apparatus for ore concentration by gas flotation, consisting of two adjacent mixing-vessels each containing a rotating agitator and a spitzkasten contignous. Claims 3, 4, and 5 cover a number of these elements.

1,067,485. Nutter *et al.*, July 15, 1913. Process for concentrating ores consisting of agitating water containing mineral-frothing agent, removing the froth, agitating pulp again with addition of another agent, producing another froth, "and so on."

1,084,196. Broadbridge *et al.*, January 13, 1914. Apparatus for agitation-frothing process comprising a series of agitating and aerating vessels and a series of spitzkastens.

1,101,506. Bradford, June 23, 1914. Introduces flowing mixture from mixer into a centrifugal pump, adding sulphuric acid and air and steam. Agitates to form a froth.

In all these patents the Minerals Separation is the assignee and the gradual advance is noticeable from the first claim of one vessel to the next claim for two mixing-vessels, then one agitation and another, "and so on." How far on is "so on"? Do they claim to use a third and a fourth vessel, and if so, must they use a different "mineral frothing agent" every time, or can they repeat with the same one? By the way, just what, in a strictly legal sense, is a "mineral frothing agent"? Does this cover any further discovery of such an agent that is thus preëmpted in advance? Is it anything and everything that will make a froth with a mineral?

Much of the phraseology of the Minerals Separation patents is vague and loose-jointed. If intentionally so, with the idea of making the most favorable interpretation in any circumstances that may be presented, the object is self-defeated, for it is an elementary principle of legal interpretation that words shall be strictly interpreted against the person using them.

This tendency is shown in Mr. Ballantyne's statement that Claim No. 1 of the Sulman patent is for the underlying idea of the various processes, introducing by some means or other air under pressure into pulp containing oil and water. "By some means or other," by any possible means, and Minerals Separation claims them all. "Agitation to form a froth" was their great claim, and in practice they seem to claim any agitation for any purpose whatever and any froth, however formed. So far has this been carried that it is said that Callow has desisted from the use of a paddle to keep his canvas clear from sand, although disclaiming any intent of forming a froth with it, because Minerals Separation takes the paddle to form a froth and proposes to keep it for all other purposes.

The present situation of flotation metallurgy is intolerable. There is every appearance that some time, perhaps years, may pass without a final judgment of all the Minerals Separation litigation and meanwhile they keep on collecting royalties from parts of the mining industry that are available for coercing the rest. Progress is halted. Development is retarded. Can nothing be done to rid the metallurgical Sinbad from this Old Man of the Sea? Statements are freely made that in case of a final Minerals Separation victory, a strict accountability will be required from all infringers.

The Norris process has given excellent results with the apparatus of both Minerals Separation and of Callow, the concentrate being of excellent grade from the rougher and from a slow stirring-apparatus after the Elmore

style of mixer. The process can be adapted to any type of tank, box, spitzkasten, or other receptacle and there is no danger of defeat from an attack on the Norris patents by the Minerals Separation. A method can be devised to float ores without using the Minerals Separation patents or paying them royalties. The day of royalties on daily tonnage is past. Arrangements can be made freeing the industry from this toll and also from extravagant prices for patented machinery.

The suggestion has recently been made that one of the most needed things in the mineral industry at the present time is some easy way of making flotation tests at the mine; so that a mill-foreman or mine-boss may be able to make his tests on his ores and decide whether or not they are susceptible to flotation and then design a process for treating them. Of course, any accomplishments that a foreman or mine-boss may have, add to his value; and ability to set a broken leg or cure a case of mountain fever might earn for him an additional salary, but aside from 'first aid' to the injured, no one would want to put himself in the hands of the foreman or the underground mine-boss for medical treatment. It is the same way with tests on flotation. Aside from mere preliminary experiments, testing ores for flotation is as much a separately professional matter as caring for a broken leg or a case of mountain fever. Metallurgical engineering is now so far advanced that there is but small reason for going astray in the matter of treatment of ores by flotation, provided adequate preliminary tests are made by expert metallurgical engineers. The cost of such tests is trifling and their importance and value not to be exaggerated.

One great reason why a mere practical millman or miner cannot devise a process from the patent claims and specifications is that most of the important elements of the actual installation are omitted from the patent. The essential principle of the patent of Elias Howe for the sewing machine was that the eye was in the point of the needle. Taking that for a starter, how far would a man get toward building a modern Singer from the Howe patent? It is like an equation in calculus. Take such an equation representing a mechanical movement and compare it with another equation of the path of a comet. Differentiate both and out go the constant factors and the differential equations might be identical in form. Re-integrate them. Do you get back your mechanical movement and your comet's orbit? You do not. Your constant factors do not re-appear. The same way with patent specifications and claims. They contain only the differentials. In fact, a recent letter from the Patent-Office said: "It is suggested that the claims eliminate all unnecessary references to structure and that they be limited to the actual process steps."

By a proper combination of interests, not only can there be avoided the payment of royalties on ores treated and high prices for patented machinery; and not only can every mill-owner be assured of the constant high efficiency of his plant, but he can be protected against infringing patents, and if sued for infringement he can be defended at a trifling cost to himself, a general fund being provided, at a small percentage of what the use of the Minerals Separation patent would cost him. The way to do is to perfect a process in a metallurgical laboratory to fit the special ore in each case. When the process is perfected care must be taken that it includes the patent principle under which it is to be licensed and does not infringe any other patent. In one mine in the Ninth Circuit where a home-made process has been patched up, it seems as though every well known flotation patent has been infringed, and yet the process will not work as it ought.

Well, suppose the program is carried out and the Norris process is generally adopted, and the Hyde and Miami suits are decided in favor of the Minerals Separation. That has no effect on the Norris process, not being a party to the present suits. A new suit would have to be brought against new defendants and another term of years passed before the Minerals Separation could hope to get any money, however favorable their case. But their case would not be favorable. The first thing that they would meet would be a certified copy of the proceedings in their own country where their own Government decided that the Norris process, although the applicant was not represented at the hearing, was not an infringement of the five patents governing the Froment, the Elmore, or the Minerals Separation processes respectively.

The Minerals Separation people were so sure of their strategic position, so confident that their American patents would be sustained by the courts that, from what seems mere wantonness, conditions were imposed upon the licensees that were intolerable; with the result of a concerted movement on the part of the whole mining industry to defeat the Minerals Separation patents and, from the present outlook, with every prospect of success.

Cost of Mining. J. R. Finlay said, during a lecture at the Columbia School of Mines: "Let us compare costs at a mine in southeast Missouri with one in Nevada, assuming that in both cases the output is at the rate of 4 tons per man per day. In Missouri, labor (at $2.60 per day) costs 65c. per ton of ore mined; power (coal selling at $2.25 per ton) costs 25c. per ton; supplies cost 15c. per ton; total cost, $1.05 per ton, leaving a profit of $1 per ton from which to deduct various general charges and interest. At a mine of the same character in Nevada, labor (at $4 per day) would cost $1; power (coal at $6.75) 75c.; supplies (20% higher than in Missouri) 18c.; total $1.93 per ton, or $0.88 higher than in Missouri. Assuming the same market-value for the ores, the profit would be respectively 12c. and $1. Hamilton Smith, a distinguished engineer thirty years ago, suggested the advantage of comparing mines on the basis of yield per unit of stoping-area. At Grass Valley, California, it costs about $5 to mine and mill a ton of ore; at the copper mines of Lake Superior it costs only $1.25, yet applying Smith's unit, the cost per acre of stoping-area is nearly alike in the two regions. The really important factor is not how many tons are mined, but how much area must be excavated."

Hennen Jennings, and Mining on a Big Scale

AN INTERVIEW. BY T. A. RICKARD

Mr. Jennings, you were born in the West?

No. I spent some ten years in California after leaving college, but I was born in 1854 at Hawesville, Kentucky, a small mining town on the Ohio river. At that time my father was the owner of a bituminous coal mine. He had come from New Orleans, where he was connected with large shipping interests.

Was the enterprise successful?

It was very tempting in that the coal outcropped along the river-bank and could be loaded by gravity-incline direct on barges in the river, but my father had no experience or training in coal mining, and the coal was found to be unsuitable for shipping South, as he had hoped. The river-steamboat market was limited, and although the mine was worked for a long time the venture proved unsuccessful.

What was your early education?

The Civil War interfered with my regular attendance at school, but my mother, a woman of rare culture, was my teacher and inspiration. Just after the war, when 13 years of age, I went with relatives to England, remaining there three or four years, part of the time at school in London and over two years at a small school in Derbyshire, at Farnah Hall, where I enjoyed a wholesome health-giving country life, and was stimulated in engineering matters by my teacher, Rev. E. E. Montford, who had love and attainment in mechanical and scientific subjects. Soon after my return to Kentucky my father died and I started to work.

What sort of work was it?

I erected a saw-mill on some timber property that had been owned by my father. I made a little money out of the lumber business and in such a way that it attracted the favorable attention of a relative who aided me in going to college.

You went to Harvard?

Yes, I graduated from the Lawrence Scientific School of the Science Department of Harvard in 1877.

That had not been long started?

The Lawrence Scientific School at Harvard is probably the oldest scientific school in the United States. It was started in 1847.

I suppose Shaler was the most interesting of your teachers?

Professor N. S. Shaler was under forty when I first met him, but his rare personality was felt by all the students who came in close touch with him. His course in geology was largely attended by the academic students as well as the scientific. His subsequent writings have shown him to rank high as a philosopher and poet, as well as a scientist. But above all, he showed himself a big-hearted human being to whom the students could turn for advice and comfort in time of trouble. One of his desires and aims was to bring the academic and scientific students in closer touch and to obtain for the future engineer a broader and more liberal education. The school was at a low ebb in point of members when I was connected with it, but some years later Shaler was appointed Dean and under his administration the scope of the work was enlarged, the social life of the students in the academic and scientific departments became more unified, and the attendance increased from 30 to over 500 students.

You were fortunate in coming under Shaler's influence?

Most decidedly. Shaler was the personality among my instructors that impressed me most. I had come to college unknown by him, but soon after my arrival he came to my room, having seen my name registered from Kentucky. He was a Kentuckian. He thought I might be lonely and came to give me a friendly welcome. He invited me to his house and I had the privilege of considering him a true friend as well as teacher until his death.

You took the course in Mining Engineering?

No. The mining course was not then well established. I took the course in Civil Engineering which gave all the preliminary training required for mining engineering, and I obtained the degree of Civil Engineer in 1877.

How did your education at Harvard fit you for your subsequent career?

The course then given has been greatly improved, but as it was it educated me in mental concentration and effort, and afforded me the foundation of the general principles in my profession.

You found plenty of mental stimulus?

Yes. I was thrown not only into contact with my own classmates, but I made friends of students in other departments of the University and also with some of the distinguished men among the teachers. At that time there were concentrated in Cambridge and its vicinity a number of men of great distinction. Charles William Eliot was then a young and active president; Oliver Wendell Holmes and James Russell Lowell were lecturers; Henry Adams, John Fiske, and William James were connected with the University in the Academic Department in their several specialties. In the Scientific Department, Benjamin and James M. Pierce and Henry Lawrence Eustis were professors of mathematics; Asa Gray was professor of Natural History; Walcott Gibbs and John Trowbridge were Professor and Instructor, respectively, of Physics; Josiah Cook, Professor of Chemistry; and Josiah D. Whitney, Professor of Eco-

nomic Geology. Longfellow was then living at Cambridge and Emerson at Concord. Naturally I absorbed some of the atmosphere created by these men.

When you left Harvard did you get a job at once?

Yes, I did, by the aid of my friend Hamilton Smith, who came from a little town in Indiana opposite my home on the Ohio river.

What was the nature of your first work?

Chiefly clerical, in connection with the re-construction and enlargement of a crib-dam by the North Bloomfield Co. in Nevada county, California. In the issuance of supplies and keeping of pay-rolls of the white men and Chinamen, I was much impressed with the accuracy of the Chinese head-men, who, with their abacus, kept accurate accounts and were thoroughly honest. This work in accountancy, coupled with what I obtained at North Bloomfield later, satisfies me that one of the most valuable experiences a young engineer can obtain is a good insight into the accounts and commercial considerations at the very outset of his career.

You were fortunate in winning Hamilton Smith's good-will?

Hamilton Smith, who was the consulting engineer, instructed me in the engineering problems of the work, and my connection with him was of great educational advantage, for he planned with daring and thoroughness. In the execution of his plans he stimulated effort in others, and in no way spared himself. Although largely self-educated, his scholarly book on hydraulics, published in 1886, showed that he was a master in the theoretical mathematics. His honesty of purpose won confidence and he was eminent among mining men both in this country and Europe.

Who else was connected with the North Bloomfield Co. at that time?

H. C. Perkins was the manager. He was a close friend and assistant of Hamilton Smith and had risen from the accountancy department of the company. His keen business sense was supplemented by his facility in mechanical details, as shown by his invention of a deflector for the hydraulic monitor. Our first meeting resulted in a life-long friendship.

Where did you go then?

I spent the summer at the English Dam and North Bloomfield. From there I went with letters of introduction from Hamilton Smith to J. B. Randol, of the New Almaden quicksilver mines. Up to this time I had been receiving a salary of $40 per month. It was now raised to $50. At Almaden I had the good fortune to become the assistant of a man who is one of the most character-building men it has ever been my privilege to know—Ross E. Browne. I re-surveyed with him the quicksilver mines, and made a topographic map. Mr. Browne left New Almaden to become instructor at the University of California, and I was then made chief surveyor. By reason of the training he had given me, I was able to come into engineering prominence through the close connecting surveys that I made in the mine under difficult conditions. This gave me my first step in the profession.

How long were you at New Almaden?

I was there in all about seven years, but with a break of two or three years. After making the survey I received an appointment as assistant to Mr. Perkins at North Bloomfield again, and I stayed with him about 18 months; after which he gave me charge of my first mine—the Ruby Gold gravel mine in Sierra county, the continuation of the Bald Mountain channel on the Forest Hill divide. At this mine we were disappointed in trying to intersect the channel, but afterward a deeper channel was cut by our tunnel, and in the finding of this, some reasonable hopefulness on my part gave me my first winning, because some of the owners abandoned the undertaking, permitting me to take some of their stock, which later proved profitable.

The mine was shut-down?

No, it was worked for several years after my departure and paid dividends under the foreman. I, however, was offered by Mr. Randol the position as superintendent of the New Almaden mine, and accepted. Randol had the reputation of being a hard taskmaster, but he proved an excellent friend to me and kept me up to the mark. The position afforded me an opportunity of working a complex lode and experience in working men on contract as well as day's pay.

Whom did you get to know at New Almaden?

While at New Almaden I first met Professor Christy, for whom I ever after retained a high regard. I came in touch with Fred Bradley, then a student from Berkeley, with Edward Benjamin, at that time model-making, and with Charles Butters, who acted as chemist for a short time while I was surveyor and engineer. George F. Becker made a geological examination of the district while I was there and I had the good fortune of again meeting him in South Africa, and the privilege of having him now as one of my Washington friends. I remained at New Almaden until 1887, when I went to Venezuela to take charge, as manager, of El Callao mine.

Were you not married in California?

Yes. I was married in 1886 to Miss Mary L. Coleman, daughter of John C. Coleman, one of the venturesome pioneers of 1850 who, with his brother, was successful in mining ventures. They were at one time chief owners of the Idaho mine at Grass Valley. Prior to this they were engaged in hydraulic mining at Iowa Hill. The soil on which was erected the house where my wife was born was later hydraulicked away, so there is a doubt whether the place of her birth is Placer county or the Bay of San Francisco.

Were you asked by Mr. Perkins to join him at El Callao?

Yes. He, and Hamilton Smith, who was acting consulting engineer of the El Callao Mining Co., arranged for me to succeed the former as manager. The mine had just passed its maximum activity; two years previous it

was the greatest gold mine in the world, yielding $200,-000 per month.

Can you give some further facts as to this celebrated mine?

The mine is situated on the Yuruari river, about 150 miles southwest of Ciudad Boliva, in Lat. 6° N. It is on the fringe of forest land near the savannas. It was owned by a Venezuelan eompany, but stock was largely. held in England, although the control was in Venezuela. It was opened up by a company of Corsiean traders, of whom one Liecioni was first president and chief owner. The existence of gold was known to the natives as far back as 1849 and attracted the attention of the Corsican owners soon after. At first it was supposed to be a gravel deposit, but in working to bedrock the vein was uneovered; there was a phenomenal amount of visible gold in white quartz, and for a length of two to three hundred feet a shoot of rich speeimen ore was found. The lode was finally exploited near the surfaee over a length of about 1000 ft. down to 900 ft. vertical. About $30,000,-000 was taken from the deposit. Work was started with small erushings in ordinary mortars and then a 10-stamp mill was erected, which was enlarged to 60 stamps before Mr. Perkins' arrival. The early erushings gave over $100 per ton, but eosts were from $30 to $40 per ton. Under Perkins' able management, and with ample funds at eommand, a new 60-stamp mill was constructed and the whole work thoroughly re-organized. The working eost was reduced to $13 per ton. At the time of my arrival the bonanza days were over and the orebody showed indieations of impoverishment.

Did the ore peter out?

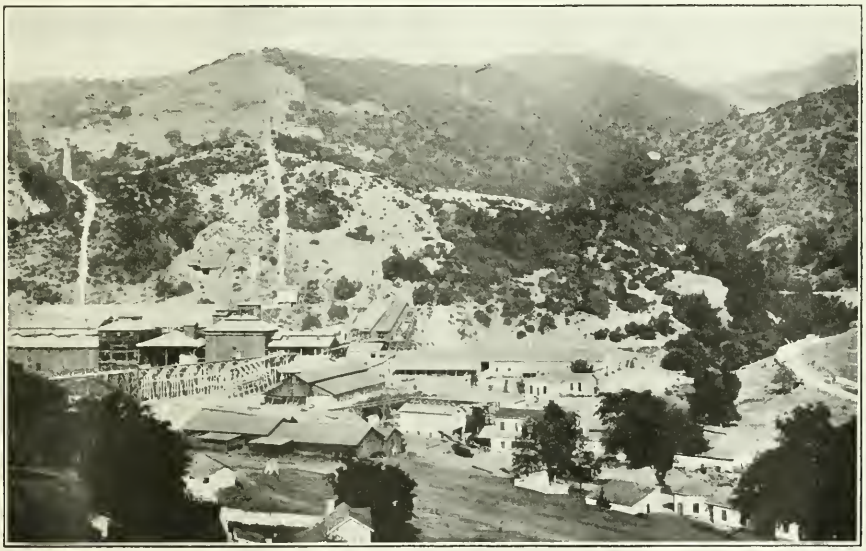
It did not peter out. Rather, it tapered out. The quartz continued, but it was not found profitable to work it.

Have you any explanation for the non-persistence of the rich ore?

The ore formation was an interesting and complex one, but difficult to deseribe briefly without diagrams, and I have no eonvincing explanation to advance as to the non-persistenee of the rieh ore.

El Callao served as a practical school of mining for a number of men, I believe. What others besides yourself?

Hamilton Smith made the first elaborate report on the property for the Rothschilds and eame in sueh elose touch with the local owners in Venezuela that he was made eonsulting engineer and brought about the Perkins management. Mr. Perkins had among his assistants Thomas Mein, who was his first mine-eaptain at El Callao, becoming later manager of the Naeupai, an adjoining mine. Captain Mein was afterward superintendent of the Alaska Treadwell mine; and then, in 1892, of the Robinson mine in South Afriea, where he was much respeeted and beloved. Louis Seymour was at Callao in connection with the machinery of the 60-stamp mill and became one of Mr. Perkins' mechaniea assistants. He was afterward mechaniea engineer at De Beers, South Afriea, then manager of Fraser & Chalmers' works at Erith, England, and again chief mechaniea engineer of H. Eekstein & Company at Johannesburg. He was the organizer of the Pioneer Engineering Corps, which repaired bridges and other construetion destroyed in the Boer War, and lost his life gallantly at Sand River.



THE FURNACES AT NEW ALMADEN IN 1886.

Who else was there, Mr. Jennings?

George Webber succeeded me as manager in 1889 and reduced operating costs to $10 per ton before his departure. He was afterward manager of the Crown Reef and then the Rand Mines in South Africa, and he, in turn, was succeeded by Barry Searls, who became manager of the Crown Deep Mines, South Africa. M. Robeson acted for a time as mechanical engineer for the Nacupai and was also my mechanical engineer at El Callao. Subsequently he became assistant to Seymour at De Beers and, at Seymour's death succeeded him as Chief Mechanical Engineer to the Ecksteins. E. A. Blanton invented the cam now so well-known in stamp-milling while at the Union mine, El Callao. Subsequently he became Mechanical Engineer at the Crown Reef mine. Robert Duncan, my foreman, became manager of the Alaska Treadwell mine. Richard Bowen became chief millwright to the Rand Mines. John Walsh, the mill-foreman, was later mill-manager at the Ferreira mine. J. Klimke, later State Mining Engineer of the Transvaal, was a surveyor in the Callao district at the time of my arrival. I became acquainted with F. H. P. Creswell, of the Chile mine, who afterward became manager of the Village Main Reef and has attained prominence in political strife in South Africa.

I suppose El Callao furnished as good experience in gold mining as could be obtained at that time?

Yes. The distance of Callao from sources of supply and the honest and progressive work there accomplished by men thrown so very much on their own resources, coupled with the command of large funds to install the best appliances, afforded a fine training.

What was the metallurgical process?

Simple amalgamation in stamp-mills. It did not pay us to ship concentrate. It was the simplest ore I have ever seen, some forty or fifty bags of specimen ore per month adding largely to the output. We used blankets and canvas tables for making a rough concentrate. Some of this was subjected to calcination or re-ground in pans or barrels with quicksilver.

How long did you remain at El Callao?

Two years. I had a two-year contract.

Your health was good all the time?

I was taken with fever two days after my arrival, but I had it in mild form. The doctor said, "You have the right fever and will never have the serious trouble that may come to people who have not been thus inoculated." My family, however, did not thrive, so they returned to New England pending my arrival. It's the everlasting heat that saps the energy of men in the tropics: the thermometer seldom went over 90°, but never below 70°. The humidity was excessive. The clearing of forest-lands and the system of housing and living at El Callao made it comparatively safe for white men. Most of those who were there during my time are still alive.

From El Callao you went to South Africa?

I first went to London, where I obtained an appointment with Jules Porges & Co., the predecessors of Wernher, Beit & Co. and the parent firm of H. Eckstein & Co. in South Africa. That was in 1889. I arrived on the Rand in December of that year.

What stage of development had the Rand reached at that time?

The first gold from the Witwatersrand conglomerate was panned in 1885. Johannesburg was founded in 1886. The first stamp-mill erected working on the 'banket' was the Wemmer in 1887. At the time of my arrival the monthly output from the mines had reached 39,000 ounces and the total return for that year was £1,300,000. The mining laws of the Transvaal were liberal and definite. Feverish pegging of claims had taken place in all likely localities. Boom hopes and market quotations had soared high, but were on the wane; market depression had set in and continued for some three or four years, during which time much good constructive work was done. Not many mines showed a substantial net profit, in spite of high yields. No railway had then reached Johannesburg and the cost of working was extremely high, while extractions in the mill were painfully low. The workings were just entering the pyritic zone, for example, in the Percy and Jumpers mines. Everybody was anxious about the continuation of the deposit and was questioning the proper method of treating the pyritic ore.

At what depth was this pyritic ore intersected?

At between 50 and 250 ft. down. The average gold recovered at that time was not over 60%, but the tests that had been made showed that the extraction by amalgamation was just about as good on the pyritic as on the oxidized ore.

What was there to supplement plate-amalgamation in the mills?

Only blankets. There was no systematic treatment of the concentrate. It was stored for future treatment. Several processes were being discussed, for instance, the Vautin, which was chlorination under pressure. The chief producing mines then were the Robinson, Crown Reef, Langlaagte Estate, Jumpers, Durban Roodeport.

How much were these mines producing?

There were about 40 mines with stamp-mills at work, averaging about 20 stamps per mine. The Robinson was the richest mine, with 40 stamps treating about 4000 tons per month, a yield of about £28,000 or £7 per ton. The Crown Reef, with 70 stamps, treated about 4800 tons, yielding only 33 shillings per ton. The Langlaagte Estate, with 70 stamps, was crushing about 6000 tons for a yield of 70s. per ton. The average yield for all the mines for December was 3900 oz. at 63 shillings or $15 per ton.

What was your position?

I was engaged as consulting engineer to H. Eckstein.

Can you give some facts about this firm and your connection with it?

The firm of H. Eckstein was a branch in Johannes-

burg of Jules Porges. Julius Wernher was connected with Porges in diamond-mining at Kimberley as early as 1876. In 1884 they formed a close connection with Alfred Beit—a most fortunate combination. The latter became the Kimberley representative of the firm, while Wernher went to London. Beit had great intuition and imagination, while Wernher had great sagacity and prudence. Beit was the valve-gear and Wernher the fly-wheel of the firm of Wernher-Beit, which took over the business of Jules Porges & Co. soon after my arrival in South Africa. Hermann Eckstein came to Kimberley before Beit was associated with Porges.

And Beit became the coadjutor of Rhodes?

Yes. Beit was a great believer in and friend of Cecil Rhodes, and without his aid it is doubtful if Rhodes could have accomplished the amalgamation of the diamond mines. At Kimberley these men were also thrown into contact with J. B. Taylor, Lionel Phillips, and George Rouliot, all of whom became members of the Eckstein firm and had dealings with J. B. Robinson. They became acquainted with American engineers in the sterling personalities of Gardner Williams and Louis Seymour. They were also all friends of Dr. Jameson and each other, for early experiences knit people together. Financed by the Porges firm, H. Eckstein and J. B. Taylor opened an office at Johannesburg in 1887 under the name of H. Eckstein, the title being changed to 'H. Eckstein & Co.' after the death of Hermann Eckstein in 1893. Friedrich Eckstein joined them in 1888 and Lionel Phillips in 1889. George Rouliot, Percy Fitzpatrick, Raymond Schumacher, and others were given interests at considerably later dates. I received a cordial welcome from Taylor and Phillips, and a few months later a hearty one from the Ecksteins.

These must have been able men?

Indeed they were. Hermann Eckstein was made the first president of the Chamber of Mines in 1890. Besides being a keen man of business, he was most generous and kind-hearted. The Ecksteins were sons of a Lutheran clergyman and were born at Stuttgart, South Germany. Hermann Eckstein's death in 1893 was a great loss to the Rand. Subsequently, Friedrich Eckstein took a prominent part in the business. He is fortunately still alive and has much of his brother's ability and kindliness. Both Taylor and Phillips have won distinction and remain close and loyal friends.

MINING ON THE OUTCROP OF THE BANKET AT THE FERREIRA MINE IN 1888.

How did the firm of Wernher, Beit & Co. acquire its big control?

In 1886 Beit financed J. B. Robinson in his purchases of farms on the Rand and in return the firm received large holdings in the Robinson, Langlaagte, and Randfontein properties, but they so traded that their holdings in the Robinson mine became their dominant one. Besides interests in the above mines at the time of my arrival they controlled the management of the Ferreira mine, then in the equipment stage, and had large holdings in the Crown Reef, Jumpers, and Bantjes, and considerable 'deep-level' ground. They made big profits in the boom 1888-1889, but as they believed in the future of the goldfield, they were desirous of giving the mines they were connected with every advantage that science and money could furnish. They endeavored to place the high capitalization due to the boom on a solid basis of actual returns. They took all risks in initial stages and floated no companies that had not intrinsic promise. They asked no reports from their technical staff for flotation or stock-market purposes. They encouraged the collection of statistical information, which was given freely to the public to an extent not elsewhere known in the mining world. The returns from the mines were given under oath. They trusted fully and rewarded liberally those that won their confidence and approval. I consider it a rare good fortune to have been thrown with these men as I was, and to recall my pleasant and cordial relations with the original members of this firm, which continued for 16 years without rupture except by death. The untimely deaths of Hermann Eckstein in 1893, Beit in 1906, and Wernher in 1912, robbed me not only of honorable, powerful, interesting business associates, but also of kindly loyal friends.

The initial success at the Robinson and the Ferreira encouraged them to obtain controlling interests at low prices in languishing mines or those on which work had been suspended, such as the Crown Reef, New Heriot, City & Suburban, Village Main Reef, Salisbury, Henry Nourse, New Modderfontein, Nigel, besides deep-level companies, etc., for all of which I acted as consulting engineer, as well as for the Robinson. By liberal financing and good management these were placed on a most prosperous basis.

The fruit of their policies is seen from the returns of the Eckstein group of mines in 1911 prior to the death of Sir Julius Wernher. The output of the Rand for that year was approximately £34,000,000 from about 24,000,000 tons crushed, of which over £12,000,000 was produced by the Eckstein group crushing nearly 9,000,000 tons. The men employed during this year numbered about 25,000 white and 190,000 natives, or more than is employed in all the gold, silver, copper, lead, and zinc mines in this country. The Eckstein group worked about 8000 white and 56,000 natives, and earned over 40% of the dividends declared.

What were your first impressions of the Rand?

I went to the Rand with little knowledge of the work already done and with no preconceived ideas as to how it should be done. My brother came out with me, but he went to the Willows silver mine near Pretoria, then to Kimberley, and did not enter gold mining until 1893. I brought with me no assistants, but soon obtained the efficient aid of Arthur Wilkinson, the secretary of Eckstein, also of Fernside Irvine, a Scotch mechanical engineer, John A. Dennison, a young Englishman, also Hugh F. Marriott, a graduate of the Royal School of Mines, who did excellent work in connection with the early bore-holes. I realized at once that the Rand presented different conditions than any that had theretofore occurred in my experience or reading, and I was frank enough to beg for time to educate myself on the spot. I did not attempt a comprehensive report of my views until March 1890. The report was conservative. It gave warning as to boom values, but showed confidence in the future of the goldfield; it advised that profits should be moderately estimated and carefully striven for. Time was taken to educate myself and then my principals that it was right and necessary to spend largely in order to reap bountifully, but this was soon fearlessly done on a great scale.

What metallurgical advice did you give?

At that time nobody realized the great downward continuation of the ore, nor did we know how best to extract the gold. I knew, and others knew, that by increasing the number of Frue vanners such as were used in the Robinson mill, and by using more blankets, we could increase the extraction. This was done, and it was also decided to treat the concentrate by chlorination.

Was that when Charles Butters was engaged?

Yes. I had known Butters in California, and he was also known to the other Californians, so a telegram was sent to Perkins, who offered him an engagement.

When Mr. Butters arrived you proceeded to erect a chlorination plant at the Robinson, I presume?

Yes, and that plant eventually proved successful. Before its construction James S. MacArthur, J. H. Cordner-James, and Alfred James came to the Rand and gave us an opportunity to test the now famous MacArthur-Forrest process of cyanidation. Alfred James took a leading part. The first test-plant was erected at the Salisbury mine in 1890. As a representative of the Ecksteins, I was given the first opportunity to ascertain the efficiency of the process.

What plant did they have?

They agitated with paddles in tanks, but on a small scale. The plant gave no opportunity of determining the cost of working on a large scale, but it did afford facilities for determining the extraction. I watched the work with my assistant, from the charging of the tanks to the final clean-up and was much impressed with the result.

That was an historic occasion, Mr. Jennings?

Yes, indeed. I had the opportunity of being thrown into intimate contact with MacArthur and Alfred James. MacArthur was a most modest man, and impressed me with his quiet ability. The only claim he made for his

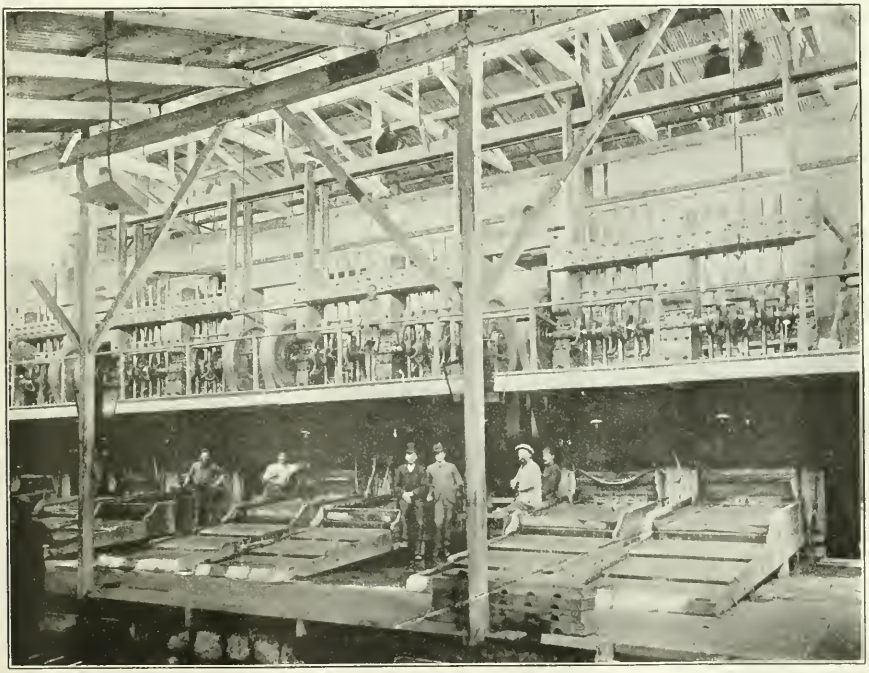
part in the discovery of the process was that he had suggested the means of precipitating the gold. The idea had occurred to him through seeing workmen making shavings from a big plate of zinc. He conceived the idea of using zinc shavings in a compact form instead of precipitating on a big plate area. Thus he made the process practicable. Of course, the theoretical knowledge of the solution of gold by cyanide and the precipitation of the gold on zinc was a matter of encyclopedic record. MacArthur's adoption of the use of dilute solutions was the key to the usefulness of the process.

What did the people on the Rand think of it?

The fact that the cost was not given prevented the ward given the right to work the process itself at a minimum royalty. This was duly arranged.

Who built the first cyanide plant?

The first cyanide plant on the Robinson mine was designed by Alfred James and MacArthur, and in that plant all the fundamental principles now to be seen in modern practice were in evidence. Of course, subsequent work has immensely improved the details and lowered the cost. This plant was placed in charge of G. A. Darling, one of the men brought out by MacArthur. That was in 1891 and 1892, after which the Robinson company took over the plant and started a larger reduction works, the designing of which was



INTERIOR OF THE ROBINSON 40-STAMP MILL IN 1889, SHOWING BLANKETS USED FOR ROUGH CONCENTRATION, THE SAND RUNNING TO WASTE. TOTAL RECOVERY ONLY 66%. YIELD, 7 OZ. GOLD PER TON.

companies on the Rand from taking it up at once. I found out afterward that the extractions obtained in the initial test were confirmed by practice on a large scale. At that time MacArthur was aware of the need of fine grinding in the obtaining of high extractions. The cost of these early experiments must have been over 30 shillings per ton, so that it was no wonder the owners of the patents were desirous of keeping them secret, and it was this high cost that caused MacArthur and his friends to discard agitation.

Did your firm make any arrangements with them?

Yes. Eckstein & Co. expressed willingness to have the accumulation of tailing treated on a sliding scale by the owners of the process, provided the firm was aftergiven to Charles Butters, who had shown such skill and energy in connection with the erection of the chlorination plant. Mr. Butters was limited in the size of his tanks to the maximum then known to be successful in operation, namely, a diameter of 23 ft. He introduced the bottom discharge.

What was the position of Alfred James in this business?

He was the brother of Cordner-James, who had the patent rights in South Africa with Webster. Alfred James was associated with the Cassel company—as was MacArthur—and he was a great factor in the designing and starting of the Robinson plant, which may be said to have been the first large cyanide plant erected on the Rand.

This first plant then was for the treatment of accumulated tailing from the ore mined in the oxidized zone. Did not the oxidation interfere with the cyanidation?

Certainly it did. The acid had to be neutralized with lime. In the extraction given by MacArthur it was shown that pyritic concentrate as well as tailing could be treated successfully, and one of the first plants to do this was that at the Nigel mine.

Who was the metallurgist or manager of the Nigel?

Richard Gluyas was the manager, but the plant was erected and for a time run under the direction of my assistant, Fernside Irvine.

What about the direct filling of the tailing into the cyanide tanks?

The first attempt, which was under my guidance, to accomplish the continuous treatment of the product from the stamp-mill was made in 1893 at the Salisbury mine, where square wooden tanks were used in connection with an hydraulic classifier that separated the slime from sand. The practical success of the method was only demonstrated later at the New Heriot and Nigel plants with round tanks under the control of W. K. Betty and Fernside Irvine. J. Harry Johns, of the Ferreira, a Cornishman, and graduate of the Royal School of Mines, was a co-worker and friend, and lent me aid in this and other work during my stay in South Africa. The method was finally adopted at all the mines, an improvement over the original hose-filling of the tanks being made by the Mein-Butters distributer.

Did you use concrete or cement vats?

The first tanks of great diameter—40-ft.—were constructed at the Langlaagte Estate under the direction of George Richards, manager, and John R. Williams, metallurgist. The latter afterward had charge of the square concrete cyanide-tank plant at the Crown Reef and made the first successful treatment of slime by the decantation process there. He was also for some years directing metallurgist for the Eckstein group of mines. Square concrete cyanide tanks were also erected at the City & Suburban mine.

What other metallurgists can you mention?

In the metallurgical department of our firm were two other men who came out with Alfred James and MacArthur, namely, W. K. Betty and S. H. Pearce. They were prominent in the subsequent development of the cyanide process, Betty introducing an effective method of increasing or stimulating the extraction in the zinc-boxes. Fernside Irvine, my assistant in the firm's mechanical department, became also most proficient in cyanide construction work. Alfred L. Simon was another able chemist employed by us who experimented with the Malloy sodium-amalgam process. William Bettel came out for the Willows Silver company and worked for some years at the Robinson. W. W. Mein took charge of the chlorination work shortly after Butters left the Robinson employ. Some other well known chemists on the Rand, but not with my firm, during my stay there, were Andrew F. Crosse, W. R. Feldtmann, A. von Gernet, and H. F. Julian.

My understanding, Mr. Jennings, is that you were one of the first to introduce electric power on the Rand?

No, I do not think it quite accurate to say "first," but the new plant which I designed at the Crown Reef mine used electrical appliances more extensively than any other mine at that time on the Rand. Besides large underground and surface return-water pumps, the tramming from the mine to the mill was electrically done, and small motors were used in various ways. In this work I had the enthusiastic co-operation and assistance of Herbert Davis, the electrician, and the loyal energy and hearty co-operation of the general manager, George E. Webber, who had followed me to South Africa from El Callao, and who afterward became general manager of the Rand Mines.

Mr. Jennings, I would like to ask you about the deeper development of the Rand. When did you realize that the Main Reef series would persist to a great depth?

The persistent optimist in regard to the continuance of the ore in depth was Alfred Beit.

But surely Beit's optimism was founded on the advice of some engineer?

Yes. The first exponent of this belief was J. S. Curtis, at the Village Main Reef, where, in 1890, the depth of the banket was proved by a bore-hole to 530 ft. The piece of the banket pierced is now on view at the Exposition. The Rand Victoria bore-hole was sunk in 1893 and proved the continuity of the ore to a depth of 2300 ft. The Bezuidenville hole intersected the South Reef in 1895 at a depth of 3100 ft., the Turf Club hole in 1901 intersected it at 4800 ft. In this diamond-drilling I received valuable assistance from Hugh F. Marriott. In the deep bore-hole at the Turf Club hole we used his ingenious device for indicating the diversion of the bore from the straight line and were astonished at the extent of the deviation. All this drilling proved unmistakably that the southern strata of the Main Reef system are continuous wherever observed, and with them the gold-bearing banket. It showed also the tendency of the lode to flatten, and made it possible to lay out plans for future workings.

In other words, you were able to foresee the change of dip on the evidences of a synclinal structure?

This was known to me and to many other engineers, but it was first estimated closely by Hamilton Smith during his visit in 1892. The estimate that he then made of the value of gold in the banket to a depth of 3000 ft., and for only the richest section of 11 miles, was £350,000,000. This, considering all the circumstances, was a bold and far-sighted prediction, although under the mark, as the goldfield from 1887 to June 1915 produced £435,000,000. He wrote an article on this subject for the *Times* and that, no doubt, did a great deal to establish public confidence.

When it became apparent that the lode would persist, your firm formed a consolidation called 'The Rand Mines,' did it not?

The Rand Mines as a corporation was not formed until 1892. Interest in considerable deep ground on the dip from the richest mines had been secured by my firm prior to my arrival. At that time the public had lost faith in deep-level schemes and some were abandoned. After my arrival large areas farther on the dip were either purchased at low prices, pegged out, or acquired by amalgamation. In this way some 1700 claims, or about 2000 acres of ground, was obtained that commanded the dip in the choicest districts of the Rand, and at moderate depths. The capitalization of £400,000 represented only the cost-price of the ground, without equipment. Prior to the arrival of Mr. Perkins in 1893 I acted as consulting engineer and laid out some of the I have mentioned were developed and equipped on a scale demanding an outlay of six or seven million sterling, working 1300 stamps and crushing nearly 2,500,000 tons per annum, yielding over £4,000,000 per annum.

Now, Mr. Jennings, I am going to ask you a delicate question. Do you believe that the ore, that is to say, the banket containing enough gold to be profitably exploited, will persist to a uniform depth on the Rand of, say, 5000 ft.? Do you not conclude that the evidence already available indicates that the Main Reef series is becoming poorer in depth?

That, of course, is a most difficult as well as delicate question, especially as I have not been on the Rand for more than 12 years. Statistics plainly show the falling off in yield from the early to the later years, the average dropping from 42 shillings per ton in 1890 to 27 shillings

SLIME AND CYANIDE PLANT OF THE GELDENHUIS DEEP.

first shaft-work. Mr. Perkins was given full control, and under his administration, lasting some three or four years, nine subsidiary companies were either started, developed, or partly equipped, namely, the Glen, Rose, Geldenhuis, Jumpers, Nourse, Ferreira, Crown, Langlaagte, and Durban Roodeport 'deeps.' Under his direction the first great advance in the speed of shaft-sinking was made, but was afterward exceeded by the Gold Fields group when more than 200 ft. per month was sunk in some of their large shafts. His construction work was done with despatch and economy, but he left the Rand after the Raid and saw only the Geldenhuis Deep started.

But, if I remember correctly, the Geldenhuis Deep was something of a frost?

I suppose it was. Considerable disappointment was first experienced in the Geldenhuis Deep, due to difficulties in cyanide work, and also in the yield, but in the end, through Mr. Webber's efforts and more extended development work, the mine was brought to a successful issue, as is shown by the records. In the end the mines in 1914. This certainly puts up danger signals, and while there is no doubt that the ore very near the surface was richer than that at any considerable depth, yet selective mining was rightly and naturally done in opening out properties under adverse economical conditions. The reduction of working costs justifies the working of more and more low-grade ore, so it becomes a difficult proposition to know whether the falling off is due to impoverishment in depth or to less selective mining of the ore, or to both. The greater the number of stamps erected, the more temptation there is to work some unprofitable low-grade ore to keep them going.

From the deepest shafts and bore-holes it is evident that there is some profitable ore at a depth below 5000 ft. and before the exhaustion of the goldfield it is probable that the average working cost will be very materially reduced, and thus will allow even leaner ore to be worked. The water in the deepest workings does not present a serious problem; pumping and winding machinery has been so perfected that in this department low cost even at great depth can be looked for. But,

even as Methusaleh died, so also must the Rand, and if it survives a decreasing yield, then increasing temperatures and numbers of stamps must drive out workmen and wear down the present deposit so that in twenty or thirty years there will be little left to exploit at large profit.

Can you tell me anything about the starting of technical societies on the Rand?

The first technical society on the Rand was the South African Association of Engineers and Architects, formed in 1892, of which I had the honor of being first president; S. J. Farrar and A. H. Reed, were Vice-Presidents, E. P. Rathbone, Treasurer and Secretary, J. S. Curtis, T. Reunert, C. Aburrow, and G. R. Andrews, Members of Council. It was started in a modest way, but finally developed into an important society and the title changed in the year 1898 to South African Association of Engineers, as less than 10% were architects. Under its auspices Behr's paper on 'Winding from Great Depths' was brought out and discussed in such an intensive way that it finally resulted in a special volume in the proceedings of the Institution of Mining and Metallurgy in London.

In addition to this society there was formed in 1894 the Chemical and Metallurgical Society of South Africa, of which the early presidents were William Bettel, Andrew F. Crosse, W. R. Feldtmann, John R. Williams, and Charles Butters. This society was very much of a live wire and had much to do with the development of the cyanide process, as in its proceedings many papers on the various details of this process were presented and most energetically and candidly discussed.

I believe these societies have been very instrumental in stimulating and extending the usefulness and advancement of technology. Their early meetings were animated, they brought the technical men of the Rand in closer touch, and made their work and characters known to each other and to the world.

What were the first steps taken in technical education in South Africa?

Nothing was done under the Boer rule in the Transvaal in this connection, but a good start was made in 1896 in a divided course at Cape Town and Kimberley. The War interfered with this work and after the War the school was consolidated with one started at Johannesburg about 1904. The one at Johannesburg had its rise in the interest Lord Milner took in technical educational matters in the Transvaal and the formation by him of committees and commissions to look into the feasibility of starting such institutions. The first committee, of which I was a member, was formed in 1902. I was also associated with Professor Henry Miers—now Sir Henry Miers of London University—in an advisory capacity. Night-schools were started and work done on a small scale. Prof. James G. Lawn of the Kimberley School initiated some of the earlier work. Prof. Hele Shaw, of the University of Liverpool, was sent out in 1904 or 1905. The school gradually expanded in temporary quarters, but the grants of a building-site by the Government permitted the erection in 1909 on Plein Square of an imposing building costing $300,000, equipped with all up-to-date laboratory appliances. In this building is housed the Seymour Memorial Library, with an endowment of $50,000. A hall of residence, Sunnyside, is provided for the Dean and students in the suburbs, and it is interesting to me to remember that besides serving as a residence of the High Commissioners, it was before its enlargement, my home. This institution is now able to give valuable mining technical instruction in connection with access to the various mines.

What were the relations of the American engineers to those from other countries?

In 1887 the total gold output of the world was about $107,000,000, while for 1914 the output of the Rand alone was in the neighborhood of $165,000,000, and of the world, $455,000,000. This phenomenal advance in the local industry brought in its train an urgent need for men from abroad experienced and trained in gold mining. This statement on its face also demonstrates the necessity for cultivating and advancing local talent. The Rand attracted engineers from all over the world. The American engineer was favored in the start through Hamilton Smith and H. C. Perkins, who were connected with the Rothschilds and who were also in touch with H. Eckstein & Co. and the De Beers Co. Through them Gardner Williams and Louis Seymour came to Kimberley, where the leading Johannesburg capitalists had their start, and myself and others to the Rand.

The English engineers, managers, and technical men were early on the spot and were strongly represented by such men as Sydney J. Farrar, J. Harry Johns, Fernside Irvine, Theodore Reunert, O. Lentz, C. J. Alford, J. Herbert Davis, Edgar P. Rathbone, E. J. Way, George Richards, G. A. Goodwin, H. R. Skinner, J. M. MacFarlane, Laurie Hamilton, F. Spencer, C. Rowe, A. R. Sawyer, K. D. Griffiths, E. H. Melville, G. R. Andrews, and later by Hugh Marriott, R. J. Frecheville, S. J. Speak, Stanley Clay, F. H. Hatch, S. J. Truscott, S. Hancock, David Gilmour, Kenneth Austin, E. F. Laschenger, and W. H. Wood. I must not omit the name of F. Raleigh, the secretary of the Crown Reef and afterward chief assistant to Mr. Webber. J. H. Curle was mill-man at the Nigel for a time while I was consulting engineer.

The Eckstein firm was instrumental in bringing to the Transvaal a large number of American technical men, among whom in earlier years were (in this list names of those arriving after 1903 are not included): 1887, J. S. Curtis; 1889, Sidney J. Jennings; 1890, Charles Butters, Joe Richard, John Walsh; 1891-2, Thomas Mein, O. H. Hahn, R. H. Harlan, W. W. Mein; 1893-4; H. C. Perkins, George E. Webber, E. A. Blanton, G. B. Poore, Richard E. Bowen; 1895, W. H. Hall, Eugene Hoefer, Palmer Carter and Lane Carter; 1896, Louis Seymour, J. S. Price, W. Bradford, and later, H. S. Stark, R. C. Warriner, and Maurice Robeson.

John Hays Hammond came out in 1893 for the Barnatos. He soon changed to the Gold Fields group and

introduced a number of Americans, among whom were George Starr, for the Barnatos, and Victor Clement, Pope Yeatman, H. H. Webb, R. V. Catlin, H. C. Behr, and Ernest Wiltsee for the Gold Fields.

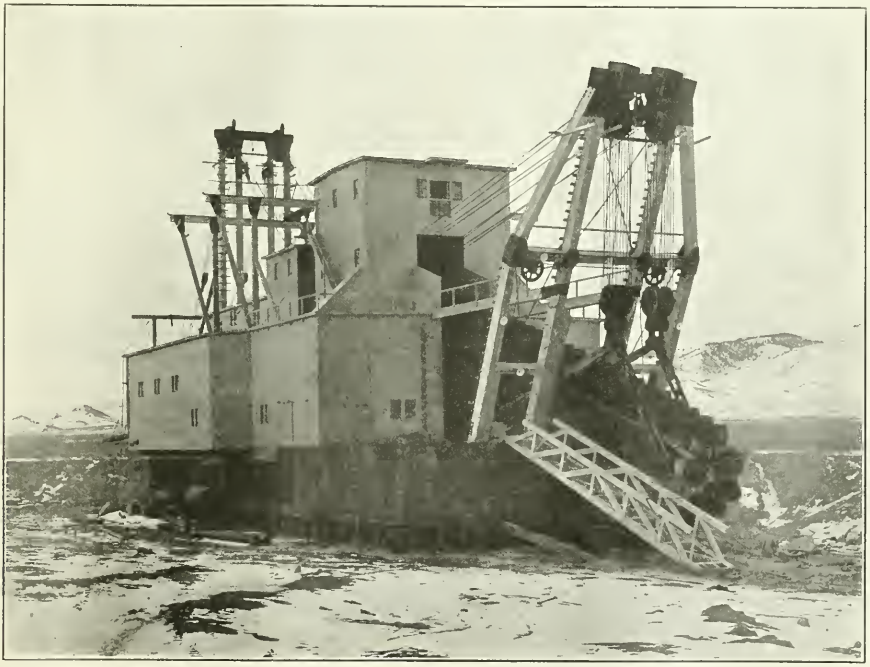
The Neumann group obtained in T. H. Leggett and F. Hellmann two other prominent American engineers, and George F. Becker, of the U. S. Geological Survey, made for them a geological report.

There were not many engineers of other nationalities: notable among these were J. Klimke, a Hollander, State Mining Engineer, R. N. Kotze, also State Engineer, a native of the Transvaal, H. Islin, Swiss, Schmitz Dumont, L. De Launay, a professor of the Ecole des Mines who wrote a treatise on the mines after his visit, as did Bergrath Schmeiser, a German government engineer.

Good relations existed between these men of diverse origins?

In the early years there was plenty of work for all who came to the Rand with good technical experience, and there was most cordial relations existing between the different technical men. The great influx of Americans was most generously received and treated by their English kinsmen. Certainly, I have reason to acknowledge the great kindness extended to me by them in both the Transvaal and London.

It was self-evident that it was wasteful, and soon impossible, to continue indefinitely the importation of expert talent from abroad and that the natural and right thing was to train the younger men while advancing the older ones that had demonstrated their ability. The sending of Royal School of Mines students from London and the founding of technical teaching in the Transvaal was certainly a right step for student-training schools. Many of these showed exceptional talent and it was a pleasure to advance them. At the time of my leaving I was gratified to see what able managers had been developed on the Rand. In consequence of this policy the American engineers who returned to their own country were not replaced by new importations and thus, at the present time, the number of American engineers on the Rand is far smaller than ten or twelve years ago. It is gratifying, however, to look back on the work done by Americans and see how they have done their full share in bringing about the great achievements of the Rand. Any impression that the American technical men did it *all* must be set aside. Taking all the names previously mentioned, it would be quite impossible, impolitic, and presumptuous to attempt in any way to adjudicate individual praise to the engineers, managers, and technical men cited. The results and history of the greatest goldfield in the world, more eloquently than any comment from me, speak for them.



ONE OF THE FOUR CONREY DREDGES. BUCKET, 16 CU. FT. DIGGING-MOTOR, 550 HP.

I would like to ask you if you think the Rand is a good training-school in preparation for other mining regions. Do not the relative uniformity of the ore and the big scale of operations militate against the

engineer's usefulness in districts where these conditions do not obtain?

The Rand has been a very limited school of late years for giving initiative in the investigation of new properties. Current methods in the Transvaal have been standardized by the great similarity of the problems to be solved at the various mines. however, it did and should still present a splendid field for experience in the handling of men and material on a large scale, and also in administration.

How about the Chinese experiment? Do you think that the introduction of the coolies was a wise step?

There were none in the Transvaal at the time I was there, but from reliable information I infer that it marked an advance in the application of low-grade labor. Even at a higher wage, the work of the Chinese averaged better than that of the Kaffir or native black African.

In other words, you consider that it was a pity that the importation of Chinese was stopped?

I do, on economic lines; and I see no moral ground why this scheme should have been abandoned.

When did you leave the Rand?

I left with my family in 1898 and went into the London office of Werther, Beit & Co. of which H. Eckstein & Co. was a branch. After the War I returned in 1902 and spent a year in aiding in the re-organization of the mines. My brother Sydney was then acting consulting engineer of the firm.

Did you find the work after the War interesting?

Most intensely so, as Lord Milner had initiated new constructive ideals and methods in all branches of civic life in Johannesburg. The mines had to be valued under new conditions and more broad and permanent lines laid down for their working. The deep-level problem had to be re-adjusted on a bigger-unit basis and in this connection the discussion, in which I took part, on winding from great depths, was most educating. Taxation and new political problems had to be met and technical educational matters were initiated, as I have already described. A descriptive and statistical statement of the gold-mining industry of the Witwatersrand was compiled and prepared by the engineers of the various groups of companies for Joseph Chamberlain, Secretary of the Colonies, who visited Johannesburg in January 1903. The committee of 15 engineers who drew up this report are as under: Hennen Jennings, Chairman; G. A. Denny, F. H. Hatch, F. Hellmann, G. J. Hoffmann, W. L. Honnold, S. J. Jennings, J. H. Johns, R. N. Kotze, S. C. Thompson, H. R. Skinner, H. H. Webb, G. E. Webber, P. Yeatman, and F. J. Carpenter, Secretary.

We went thoroughly into the past history of the goldfield; the yields, working costs, and statistics of past workings; the probable number of stamps that might be required in the future; the wages, living expenses, and relative proportion of natives and white men to bring about the best results in the future. It is interesting, in looking over this most exhaustive report with its tabular statements, to see how closely the future has established some of the predictions made therein. The statistical information was gathered and put together in a short time and it was only made possible by the whole-hearted cooperation of the engineers and the companies they represented.

You were in South Africa at the time of the Jameson raid. How did it affect you?

I will not pretend to take up the causes and happenings of the Raid, which has been the subject of so much writing. I can only say that I had the rare good fortune to keep out of jail and yet to hold the respect and esteem of my friends in it. After the Raid an effort was made to bring the necessities of the mines before the Government, and an Industrial Commission of Inquiry was appointed by the Government for this purpose with Schalk W. Burger as chairman. The Commission investigated matters most thoroughly and some 33 owners, engineers, managers, railway-men, etc., were called as witnesses. I took great interest in this work, and gave direct and cross-examination testimony extending over some three days during which I attempted to summarize the history and statistics of the mining industry to that date. Although the report of the Commission was broad-minded and favorable to the mining industry, it was not thoroughly acted upon by the Government. The Jameson raid started ill-feeling among the Boers, and this was fostered by their unrestricted importation of arms for three years, which of necessity meant war, as I realized before my departure.

After returning to London, on your leaving the Rand again, how long did you remain in England?

I remained with the firm until my departure to the United States in 1905, in the interim, however, making a visit to the El Oro district in Mexico. While in the London office I had many new propositions brought to my attention.

I remember you took a prominent part in the re-organization of the Royal School of Mines, and the development of mining education in London. You received the gold medal of the Institution of Mining and Metallurgy for your services in this regard, did you not?

The medal was not given me alone for my work in connection with technical education, but also for my connection with the mining industry in South Africa. In fact, the award was made before I had an opportunity of completing my work on the Departmental Committee of the Royal College of Science, but it is a generous and valued tribute from my English confreres. I received the appointment to serve on this committee in virtue of my being President of the Institution of Mining and Metallurgy in London at the time when the committee was created. My departure for the United States was made, as stated above, before I could complete my work, but our good friend Walter McDermott took my place. I consider it a great privilege to have served on this committee and believe it would have been a valuable object lesson to some of our Government committees to have

seen the dignity of the proceedings and the impartial way in which the questions were rotated to the different members of the committee and the varied lines of facts and thoughts evolved.

I believe that since your return you have, among other things, taken care of the McKay bequest to Harvard.

Yes. I have been connected with the Conrey Placer Mining Co., which started in 1898, operating in Montana, where there is now a fleet of four dredges at work, one as large as any in the world, namely, 16-cu. ft. buckets, 550-hp. digging-motor, and a 100-ton washing-trommel. This dredge in one month has dug as much as 411,000 cu. yd. from a depth of 54 ft. The dredge was evolved by a system of progressive development in dredging practice of which the early dredges started by Shaler were daring and useful pioneers. Gordon McKay, well known as a capitalist and inventor of leather-working machinery, in the initial stages of the enterprise advanced the greater part of the working capital and controlled the company. He took a keen interest in all the mechanical details of the dredges. A centrifugal pump designed by him has been worked with success and economy on several Conrey dredges.

Professor Shaler, Dean of the Scientific Department in Harvard University, acted as consulting engineer and president until the time of his death in 1906. He was active in all the affairs of the company and his geological attainments were valuable in the purchase of properties. He was also instrumental in bringing electrical power to the property. This venture brought Mr. McKay and Professor Shaler in close contact and knitted their friendship. At his death Gordon McKay willed almost his entire estate to the Scientific Department of Harvard University, but in a circuitous way, so that the University only obtains the full income by degrees. His very large interests in the Conrey company have given his estate, through dividends, retirement of stock, and interest on notes, something over $1,000,000, which should eventually enrich the Harvard Scientific Department by this amount, and should be further swelled by the future earnings of the company.

I understand that you are taking a great interest in the Pan-American Scientific Congress. What is it exactly?

This is the second Pan-American Congress, the first having been held at Santiago, Chile, in 1908. The present Congress was convened by Mr. Bryan, when Secretary of State, and is under the auspices of the State Department. The purpose is to bring together in friendly and cordial manner scientific men and societies of North and South America. An appropriation of $50,000 has been voted by Congress for the right entertainment and legitimate expenses, but this will probably not be sufficient for the publication of the papers, of which there should be a great number, and valuable. There have been a number of acceptances from South America and the Congress promises to be a large and important one.

You do not concern yourselves with the development of business relations between the Americas?

The Congress will be divided into about nine divisions, with separate chairmen. I am chairman of the Mining, Metallurgical, Economic Geology, and Applied Chemistry sections. While we have nothing in particular to do with business, we believe that the exchange of ideas will tend that way. The very fact that mining and metallurgy are fundamental industries will necessarily help business if they are advanced.

Mr. Jennings, may I ask you, did you participate in the profits of the mines with which you were connected?

Yes. In the latter years of my connection I had a definite participation in profits. My firm always encouraged me to invest in anything of intrinsic value with which I was connected. In this way I was able to make some fortunate investments, as I have never bought stock that I did not believe was worth more than I was paying for it, and I never bought more than I could pay for.

Do you approve of mining engineers speculating in mining shares?

I certainly do not believe in mining engineers or anybody buying mining shares on margin. An engineer, especially in his early career, should not lay himself open to criticism by having holdings unknown to the public in properties on which he is reporting.

Do you believe that the buying and selling of shares outright in any mine is apt to vitiate the judgment of an engineer?

Yes, I do, in the ordinary way of dealing in shares. In fact, I believe the Stock Exchange is a curse rather than a blessing to the mining industry. However, in working a property not quoted on the Stock Exchange, there is no reason why an engineer should not back his belief by putting his money alongside that of the owner.

You have had an unusually successful and honorable career; can you analyze the reason for your success?

I remember very well what Hamilton Smith said to me at the New Almaden mine when I was offered a salary of only $50 per month without board. He said: "Do not mind this salary, Hennen; do not think of your salary, but of your work, and one of these days you will be paid more than you are worth." Whatever success I have had has not been due to the possession of any particularly brilliant brain, but to hard work with interest in it, and to the coming into kindly contact with men about me, and in obtaining their assistance in the work I was directing.

HONDURAS has an area of 46,250 square miles, being larger than Pennsylvania. Its population is 600,000, of which 40,000 live in Tegucigalpa, the capital. The Pacific Mail steamers have been the only ones serving the country's Pacific coast, and service is infrequent and slow. The establishment of the gold standard would be a desirable reform; the silver peso is at present the monetary standard.

Heavy Timber Construction

By P. B. McDONALD

For the most part, the knowledge of heavy timber construction has to be learned from a boss-carpenter; there is no adequate book on this important subject. There have been articles published on the design of head-frames, trestles, etc., but this information is scattered, and many of the tricks of the trade never get into print. For instance, in the construction of a timber head-frame a mortice is the hole in which a tenon fits, but the tenon is so cut as to lack an inch of meeting the end of the hole, in order that the structure will tighten; and when the holes for the wooden pegs are bored, they do not coincide, but are non-concentric, so that the timbers will pull together, which is known as 'draw-boring.' Sometimes this space is not allowed for pulling together to make a tight structure; in such a case, a year or so after the head-frame is built, it will be liable to creak and groan when hoisting takes place, showing a loose condition—some head-frames sound like a blacksmith's bellows during hoisting.

The matter of 'sizing' and 'working face' are well

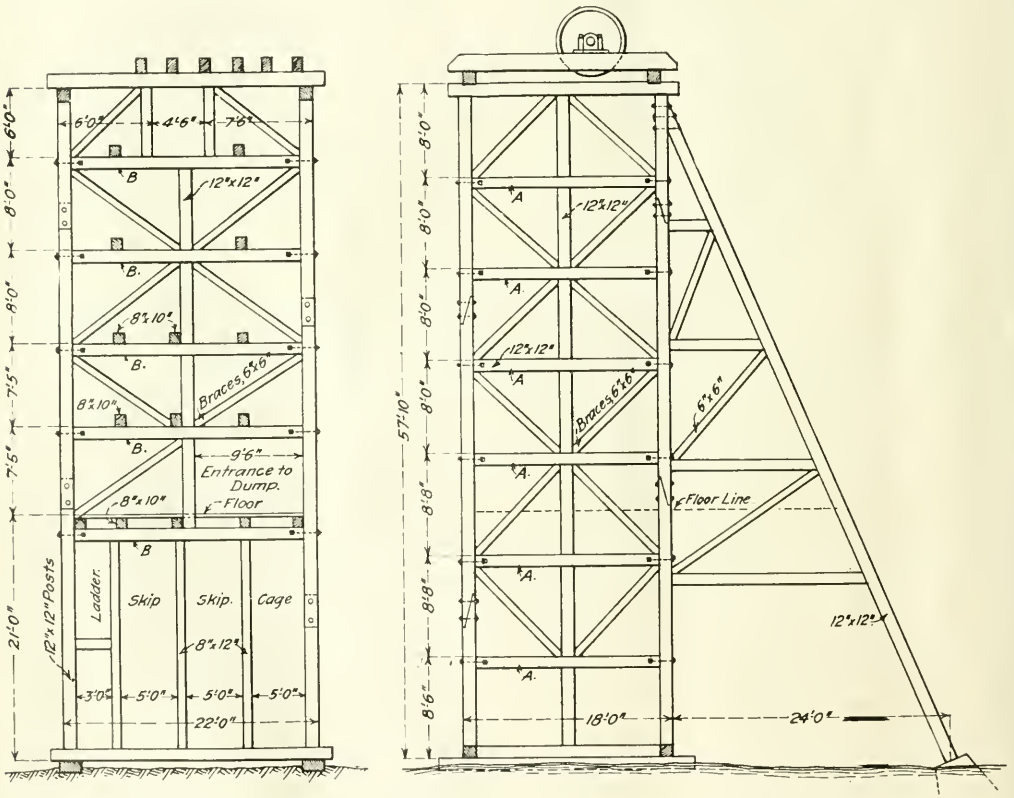


FIG. 1. TIMBER HEAD-FRAME, SHOWING EQUAL LENGTH OF MEMBERS MARKED 'B'; ALSO OF MEMBERS MARKED 'A.'

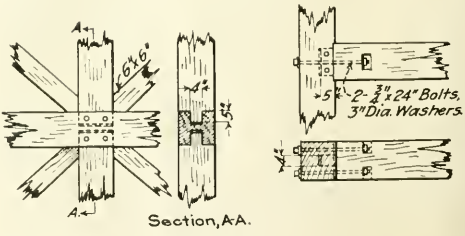

FIG. 2. DETAILS OF JOINTS.

known to a boss-carpenter, but not always to the mine superintendent. In Fig. 1, a timber head-frame is shown; incidentally, it is of the tower type with a back-brace, the original four posts being vertical. It is seen that the horizontal members marked *A* are all the same length, also the horizontal members marked *B*. Since this is so, the carpenters or timber-framers can frame up all the *A*'s at once and put them in a pile, and the same with the *B*'s. That is, any *A* should fit in any of the half dozen positions and each position does not need a certain definite member. This simplifies the work. But the posts must be exactly straight on the two sides where the *A*'s and *B*'s meet them. So a chalk-line is snapped on each post, and one face 'trued' for a 'working face,' after which the other face can be trued from it, if necessary. The truing may be done with an adze. Floor-girts have working faces trued on top. In some structures, perhaps an ore-pocket, a timber will be trued on opposite sides, indicating a centre-line.

Some details of joints of the head-frame above mentioned are shown in Fig. 2.

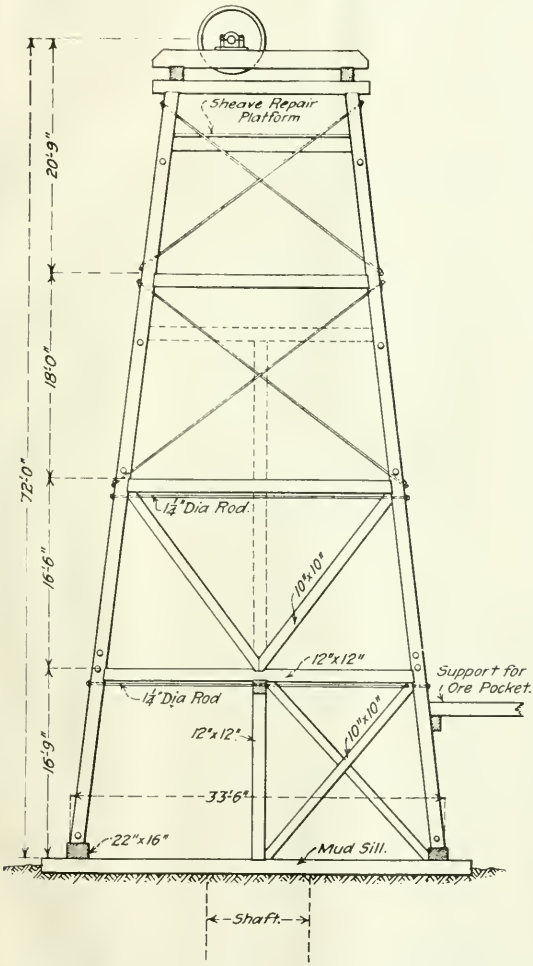

Fig. 3. HEAD-FRAME OF INCLINED-POST TYPE WITH TIE-RODS.

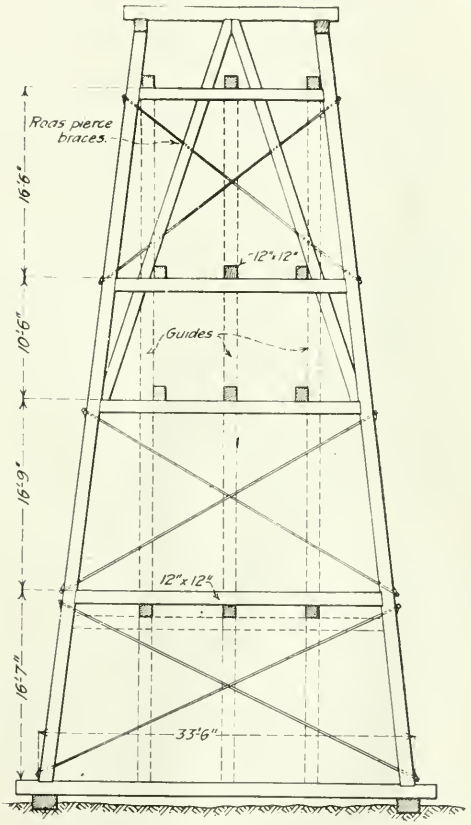

Fig. 4. FRONT VIEW.

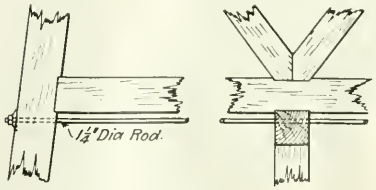

Fig. 5. DETAILS OF JOINTS.

Another simple wooden head-frame of the four-post type is shown in Fig. 3, while details of the joints are given in Fig. 5. It is seen that the posts are not vertical, and that iron tie-rods for tension members are used to

help the horizontal wooden members, and also for diagonals in place of wooden members. Such head-frames are not as economical in timber as the two-post head-frame popular in the Rocky Mountain states, and do not fulfill the technical requirements that the centre of the sheave shall be in a straight line with the back brace, but they are simple and easy to build, and are popular in regions where timber is plentiful.

For many rough structures at a mine, such as a coal-dock, and even for a small head-frame, it is not necessary that the timber shall be sawed, but round logs cut in the neighborhood can be used.

Treatment of Carnotite Ores for Radium

*The methods of extracting radium from carnotite ore as carried out in the plant at Denver have proved highly successful. They depend essentially upon the fact that strong hot nitric acid has a high coefficient of solubility for radium and barium sulphates. The method follows in brief:

The carnotite ore, pulverized to 20-mesh, is treated in a special earthenware leaching-pot with 38% nitric acid; 500 lb. of ore being used to 121 lb. of 100% HNO_3. The acid is brought nearly to boiling by means of steam passed through a glass tube and the ore gradually stirred in. Heating is continued for fifteen minutes when the acid is filtered from the ore in a stoneware filter. This is followed by a second treatment in the same leaching-pot with somewhat weaker hot nitric acid, after which the whole is washed with hot water. Nearly all of the uranium, about 50% of the vanadium, and over 90% of the radium are carried into solution by this method and separated from the bulky residue which is then discarded. The acid solution is nearly neutralized with sodium hydroxide, barium chloride, and sulphuric acid added in proper quantities and held in settling-tanks with conical bottoms for three days to settle out the radium-barium sulphate. The supernatant liquid is then siphoned into an excess of boiling sodium-carbonate solution to separate the uranium and vanadium from iron, aluminum, and calcium. The radium-barium sulphate left in the tank is filtered on a stoneware filter, washed, and dried, the washings being also added to the sodium-carbonate solution already mentioned.

The soluble sodium uranyl carbonate and the sodium vanadate are filtered from the iron calcium precipitates in filter presses and run into uranium precipitation tanks. The sodium carbonate is then nearly neutralized with nitric acid, and sodium hydroxide is added to complete the precipitation of the uranium as sodium uranate. The filtrate containing the vanadium is carefully neutralized with nitric acid, and iron sulphate is added to precipitate the vanadium as iron vanadate. Both the sodium uranate and the iron vanadate are separated from their solutions by means of filter presses. The filtrate from the iron vanadate consists almost wholly of a solution of sodium nitrate containing, of course, a small amount of impurity. This filtrate is evaporated, the sodium nitrate recovered and used again for the manufacture of nitric acid. The radium barium sulphate, without further treatment, is reduced in large graphite crucibles by charcoal, a very efficient conversion (90 to 95%) into barium radium sulphide being obtained. The sulphides are dissolved in hydrochloric acid and the residue of unchanged sulphates re-treated. The chloride solutions are crystallized in the plant in silica-lined kettles, care being taken to keep the solutions acid with hydrochlorie acid as the separation of radium from barium is much more rapid under these conditions. The concentrated chlorides carrying from 4 to 10 mg. of radium per kg. are taken to the laboratory, filtered from any insoluble impurities, and crystallized again in strong acid solution until the bulk has been reduced to a small volume, when they are converted into bromides. This is done after first neutralizing with ammonia and precipitating with hydrogen sulphide to remove the lead, which always accumulates and which is not precipitated by hydrochloric acid from strong barium chloride solution. After removal of the lead, the barium and radium are converted into carbonates by the addition of ammonium carbonate, washed, and dissolved in hydrobromic acid. From this point crystallization takes place in pure quartz dishes in solution strongly acid with hydrobromic acid.

The fractional crystallization of radium from the original chlorides to the finished product is neither tedious nor difficult, but takes place rapidly when acid solutions are used and when proper apparatus is available which will withstand their action.

A nitric acid plant has been erected which produces over 5000 pounds of nitric acid per day. Owing to the recovery of sodium nitrate the cost of the nitric acid has been very low, averaging slightly less than 2½ cents per pound. To September 1st, 4774 mg. of radium was produced in the form of sulphates and 1947.5 mg. in the form of bromide. Deliveries are continuing at the rate of 300 to 400 mg. per month.

The cost of radium figured on the basis of all the radium produced to August 1, which includes the higher costs of the earlier operations, was $37,500 per gram. The radium produced is being used in the Howard A. Kelly Sanatorium at Baltimore and the General Memorial Hospital, New York City, for the treatment of cancer and other malignant growths. A copy of the bulletin may be obtained by addressing the Director, Bureau of Mines, Washington, D. C.

*From U. S. Bureau of Mines Bulletin 104 by Charles Parsons, R. B. Moore, S. C. Lind, and O. C. Schaefer.

Scheelite when pure is a tungstate of lime. It has a hardness of 4 to 4½, with a specific gravity of 6, and a good cleavage. In color it is yellowish brown.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

A SILICA-GRAPHITE PAINT will prevent hot-water pipes from rusting, also from the corrosive effect of brine and other fumes.

ITEMIZED PARTICULARS of work performed on mining claims for assessment is not necessary in affidavits stating that such work has been done, but it is better if the important details be stated.

A SIMPLE TEST for tungsten ores is to treat a small quantity of the ground material with hydrochloric acid in a test-tube. If the metal is present a canary yellow will be seen. To make sure of the test add a scrap of tin, which will give a blue coloration.

TAMPING BALLAST under railroad-ties is tedious and occupies considerable time; but this work is made easier and better by using a pneumatic tie-tamp, consisting of a hammer weighing 37.5 lb. complete. The track settles at a rate half that when hand-tamping is employed.

MINES in the Kolar field, State of Mysore, India, have produced $214,126,000 in gold, with a bright future. They are opened to 4900 ft. vertical, the veins showing remarkable persistency. The State government sells hydro-electric power and water to the companies, receiving $973,300 per annum for this service, with taxes.

ACETYLENE, mixed with oxygen, as is well known, forms the oxy-acetylene jet used in welding or cutting metals, but according to experience of the Pacific Gas & Electric Co., it is foolish to attempt to manufacture the gases on the job. They can be bought in cylinders or tanks under pressure of 100 atmospheres (1500 lb.), costing 1.75 to 1.9 cents per foot delivered.

MANGANESE-STEEL ventilated heads for large gyratory-crushers are now made, a recent one weighing 21,360 lb. They are provided with a series of vertical flues or cores running from top to bottom, which permit a circulation of air between the wearing-surface and the shaft or spindle. This tends to prevent the transmission, from the wearing-surface to the shaft, of the heat incident to crushing. As compared with a solid head, the weight is reduced from 20 to 30%.

TUNGSTEN is ductile, paramagnetic, has the highest melting point of the metals, is practically insoluble in ordinary acids, and its tensile strength exceeds that of iron and nickel. It is used in incandescent lamps because it can be drawn to smaller sizes of wire than any other metal. Patent No. 1,163,329 has recently been granted to Thomas A. Edison for a process for forming a film for an incandescent-lamp filament. The method consists in vaporizing tungsten by an electric discharge *in vacuo*, depositing the same on a surface in the path of the discharge, and separating the film thus formed from the surface.

SAMPLING a drill-hole by dynamite was successful at a mine near Joplin, Missouri, recently. The hole was down 195 ft. in ore. A tin 'torpedo' 10 ft. long was made and charged with 50 lb. of 40% gelatine-dynamite. The two detonators were connected by insulated wire, and the whole lowered into the bore. The blast was set off by an electric battery, resulting in water and rocks being shot up 70 ft. into the air. Assays were made of the ore blown out, indicating fair sheet-ground.

EUCALYPTUS OIL is used exclusively in Australian flotation-plants, where it is cheap and efficient. According to P. W. Tompkins in *The Journal of Industrial and Engineering Chemistry*, in discussing the eucalyptus-oil industry of California, and comparing the product with that of Australia, he considers that the by-product oil of refining as well as the crude (if sufficiently reasonable and in quantities) might be utilized for the separation of metallic sulphides by the flotation process, as extensively applied in Australia. Eucalyptus oil has been used to a small extent in flotation work in California, but for the most part the oil was imported from Australia.

ACETYLENE LAMPS are largely used in mine lighting, but there are occasional explosions. The explosibility of the gas has been investigated by George A. Burrell and G. G. Oberfell, of the U. S. Bureau of Mines, who conclude that the smallest proportion of acetylene capable of propagating flame in a mixture of acetylene and air is 2.53%, and the largest proportion 73%. Acetylene, not mixed with air, is explosive under a pressure of 3 to 5 atmospheres (45 to 75 lb.) when an electric spark is passed through the mixture, or when a platinum spiral is heated in it. The danger connected with the handling of calcium carbide in a mine is remote if reasonable care is observed in handling.

COUPLINGS are those machine parts that are used to connect the ends of two shafts or spindles so that rotation of the one will produce an identical rotation of the other. They may be either permanent or disengaging fastenings; the latter are frequently called clutches. Sleeve or muff-couplings are simple in operation, holding the two shafts by a key in a keyway and sleeve; flange-couplings are also common. Disengaging-couplings or clutches may be either positive or friction-drive, the former being generally called toothed or claw-couplings. Friction-couplings usually consist of a hollow, rigid cone, and a sliding-cone, although band-clutches operate somewhat on the principle of friction-brakes. To allow 'give' between, say, a high-speed engine and a generator, a flexible-coupling is generally used.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

Butte.—Anaconda and Zinc.—Butte & Superior.—East Butte.—Alice,—Butte & Bacorn.—Butte-Ballaklava.—Anaconda and Emma.—Davis-Daly.—Butte & Zenith.

A visitor at Butte is at once struck with the bustle and air of prosperity of the place. All of the copper-producing companies are working at full capacity. The two zinc mines, the Butte & Superior and Elm Orlu, are extracting 1750 and 600 tons per day of zinc-silver ore, respectively. Developing companies are experiencing little difficulty in raising money, and claims change ownership frequently.

Construction of a 100-ton zinc-reduction plant has been started at Great Falls; it is expected to have it completed in September 1916. The estimated cost is $2,000,000. The laboratory tests were made at Anaconda, and an experimental plant with a capacity of 10 tons of zinc per day showed that the process is practicable. While details have not been fully worked out, the following system has been productive of good results: The zinc occurs as sphalerite in a granite gangue. Sulphides of iron, lead, and copper are also present in the ore. The silver-content averages about 4 oz. per ton. The ore is ground to 40-mesh, and given a dead roast. Sulphuric acid is added, dissolving the zinc, iron, copper, and impurities. Lime is added to neutralize the solution and precipitate the iron. The copper is precipitated with zinc-dust. The solution is filtered by an Oliver machine, and the zinc is precipitated from the clear solution by electrolysis. The filter-residue contains the lead and silver, and when of sufficient value it will be sent to a lead smelter. Great Falls is the logical location for a plant of this type, as plenty of cheap power can be generated.

The quantity of ore mined during the third quarter, ended September 30, was the largest in the history of the Butte & Superior company; the tonnage for October and November exceeded that of the two corresponding months of the third quarter. Work has started on one of the two new shafts to be sunk. It has been customary in the Butte district to make the large shafts with four compartments. Two of these are used in hoisting ore in counter-balance; a chippy-cage runs in the third compartment, and is used for lowering timber, and for transferring bosses and men from one level to another; the fourth compartment has the water-column, electric cables, and ladder-way. Difficulty has been experienced all over the place in keeping these large shafts straight. Even those sunk in granite at some distance from the veins cause trouble because of the tendency of the ground to get heavy. The Butte & Superior has decided to sink two shafts, one of two and the other of three compartments, with a 50-ft. block of ground between them. The two-compartment shaft will be used for hoisting ore. One compartment of the other shaft will be used for the water-column, ladder-way, and cables, and the other two will be used for the timber-hoist, which will work in counter-balance. Running the timber or chippy-hoist in counter-balance will effect a large saving of power. The shafts will be sunk from the surface to 700 ft., and will be raised from 1800 to 700 ft. Sinking is still underway in the old shaft which is down below 1800 ft. Ore is being stoped from the 700 to the 1600-ft. levels.

A vein in the Col. Sellers claim of the Butte-New York is being opened with encouraging results. The work is being done by the Butte & Superior company on its 1200-ft. level, through the Black Rock shaft.

The East Butte company started the month of December without a debt. The original debt created by the purchase of Pittsmont property was $2,000,000, all of which has been paid off from the profits of the last six years. Earnings in September amounted to $170,000, and on 18c. copper the company's profit is more than $2,000,000 per year. Preparations are being made to sink the Pittsmont shaft to the 2100-ft. level. Between 1500 and 1800-ft. level a wet, heavy fault was cut, and sinking had to be suspended until the flow of water abated. Development at 600, 700, 800, and 1500 ft. has opened ore reserves that average 4% copper. The flotation annex to the concentrator is practically complete, and is expected to be in operation on January 1. The plant now has a capacity of 900 tons per day.

Twenty-five men are working at the Alice, overhauling the surface buildings, repairing the shaft, and getting ready to unwater the mine. No work has been done on the property since last spring, when the minority stockholders brought proceedings to set aside the sale to the Anaconda company, which had traded 30,000 shares of Anaconda stock for the Alice properties, and assumed the Alice company's debts amounting to about $40,000, as has already been mentioned in the Press. The Alice litigants objected to the manner in which the Anaconda took over the Alice, and claimed that the consideration was inadequate. The court ascertained that the price paid for the Alice was $1,904,391, and as no other bid was made, the sale to the Anaconda company was allowed to stand. It was also decided by the Court that the Alice stockholders, if they preferred, should be paid in cash instead of Anaconda stock. The Alice group includes the Alice, Magna Charter, Curry, Valdemere, Rooney, Hawkeye, Reef Fraction, Magnolia, Boston, Cottonwood, Plover, Saukie Weast, Rising Star, Midnight, and other claims of less importance. It was a famous silver producer in the early history of Butte. Many of the claims are on the Rainbow lode, the big vein that is being worked for zinc by the Butte & Superior and Elm Orlu companies, and it is thought that large zinc-silver orebodies will be opened.

Efforts are being made to re-organize and raise sufficient money to pay off the debts of the Butte & Bacorn company, and provide a working capital with which to continue development. The company owns 300 acres in the north part of the Butte district, and surface indications warrant development at depth.

Two hundred tons per day of 3½% copper ore is being mined at the Butte-Ballaklava. The shaft is down 1600 ft., from which point a winze is being sunk on the vein, and as soon as it is down to the 1800-ft. level driving will commence. Development is underway at 900, 1000, 1200, 1300, and 1600 feet.

Much development work at 2500-ft. has resulted in cutting the Hesperus orebody of the Davis-Daly. About 50 tons of 5% copper ore is being mined per day, and a cross-cut is being driven in a southwest direction to pick up the faulted extension of the vein.

Development will soon be resumed at the Butte & Zenith. The shaft is down 670 ft., and the equipment is ample for a depth of 1500 ft. From the surface to 500 ft. the shaft was in granite. From that point it was sunk in a vein that is not traceable on the surface. A cross-cut north and south at 460 ft. cut four veins, all somewhat mineralized. The shaft will be sunk to 1000 ft., and the veins will be prospected at that

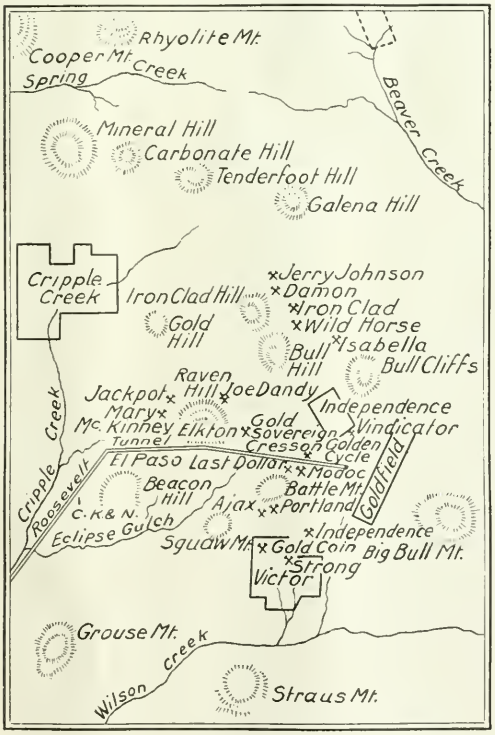
depth. The property consists of 22 claims, and is situated four miles west of Butte. The geology in many respects is similar to that surrounding the producing mines of the Butte hill. The country-rock is granite with intrusions of aplite and rhyolite. East, west, and north-west veins can be traced for thousands of feet on the surface. Walter Harvey Weed examined the property.

The Anaconda company has leased the Emma claim, which is the old silver producer at the corner of Colorado and Silver streets. Cross-cutting on the 400-ft. level has disclosed some 30% zinc ore. The vein is 30 ft. wide at that point. The showing was so promising that the Czarroma and Travonia Fraction, claims adjoining the Emma, were purchased for $250,000.

CRIPPLE CREEK, COLORADO

Weather Affects Health.—Drainage-Tunnel.—New Mill.—Freight.

The past two weeks have been so pleasant (warm and dry) that much sickness has resulted; nearly every person in the



THE CRIPPLE CREEK DISTRICT, COLORADO.

district has had a more or less severe attack of *la grippe*. In some cases so many men were away from their work on account of illness that the production of ore was likely to be curtailed. At one time it was reported that the Portland company had more than 50 men unable to report for work. With the light snowfall of the past two days the situation has been relieved, for the present at least.

According to T. R. Countryman, engineer for the Roosevelt drainage-tunnel, the advance was nearly 300 ft. during November. Soon after the first of December the flow from the portal was in excess of 15,000 gal. per minute. Since then, however, the heading has entered harder and tighter ground, and the flow has decreased to a little more than 13,000 gal. The breast of the Tunnel is now less than 500 ft. from a point directly under the Elkton shaft.

Excavation for a mill-site has been started at the foot of the main dump of the Ruble shaft on Bull hill. The Rubie Mining & Milling Co., incorporated November 27, proposes to erect a cyanide mill for the treatment of ores from the Rubie and Lafayette mines and dumps. The new mill will be called the Worcester. It will use the straight cyanide process, and will have a crushing capacity of 50 tons daily. The officers of the company are: S. A. Worcester, president and general manager; Harry L. Walker, vice-president and treasurer; S. A. Worcester, Jr., secretary; and Wm. A. Quigley and Chas. D. Gurney, directors.

A new freight rate on high-grade ore shipped from the district to the valley mills went into effect on November 24. The new rate on ores of a value of $100 per ton is $2.50 per ton, plus 1% of the assay-value, in excess of $100 per ton.

DEADWOOD, SOUTH DAKOTA

New York Capital Commences Work.—Resumption of Operations in Hornblend District.—Homestake Increases Capacity.—Wasp Tungsten Ore.

Financed by a group of New York men who have never before been interested in South Dakota mines, the property and equipment of the Imperial Gold Mining Co. has been taken over by the Ofer Gold Mining Co. ('Ofer' is the name of one of the mining claims embraced in the transfer, and so designated by its original locator, who in harking back to Bible times, got his orthography rather mixed). The Ofer company thus comes in possession of some of the choicest ground in the Trojan district, surrounded by holdings of the Trojan and Mogul company, as well as the American Express and Chicken group, on the divide between Blacktail and Sheeptail gulches. Ores are now being produced from the Burlington and Apex group, at Trojan, and from the American Express. The first-named group has been leased by the Mogul company, which, in opening a valuable ore-shoot, followed it right up to the claim line, and gladly secured the privilege of continuing into the Ofer ground. This production is of course going to the Mogul mill. The ore from the American Express is being shipped *via* the North-Western railroad to the New Reliance mill at Trojan. This work is being done by the lessees, Phillips and Carretto, of Central City. It is probable that next spring the Ofer company will either buy or erect a cyanide-plant. The old Imperial mill at Deadwood, arranged for dry-crushing and cyaniding, was constructed in the early days of this process, and is not considered efficient or conveniently situated. The new mill will be closer to the mines. W. S. Elder, of Deadwood, is general manager.

In preparation for resumption of work, the Golden West company has been re-organized as the New Golden West Mines Co. Holders of stock and bonds in the old company are to receive shares in the new one on the basis of 10c. a share for preferred in the new corporation at par; each share of new preferred carrying with it one share of new common stock. The capital is $2,000,000, one-half of which is preferred 7% cumulative dividend and the balance common, to share earnings equally with the preferred after the preferred 7% dividend has been paid. The company's property, which has many times been referred to as one of the best prospects in the Black Hills, is in the Hornblend district, west of Rochford. About 12 years ago a small mill was erected, and considerable oxidized ore mined in an open-cut was crushed, and some of the gold saved by amalgamation. When the harder, unoxidized ores were reached, some of the backers got 'cold feet' and work was suspended. It is to be hoped that the new

venture will be successful. As it is amply financed—the backers including some of the big men of the International Harvester Co.—lack of money will not be the excuse offered.

Increased mill capacity is to be secured at the Homestake by means of heavier stamps and secondary crushing. The stamps, long regarded as light, are to be increased from the present average of 900 lb., to one of 1000 lb. This, it is estimated will give about 10% additional stamp-duty. Secondary crushing will permit another 8% increase in reduction. The latter change will come with the starting of new equipment at the B. & M. shaft. Here, skips will dump into No. 8 Gates crushers, and their product carried by belt-conveyors to smaller gyratories. These changes should be completed within a few months; the B. & M. shaft equipment, new boiler-plant, etc., is nearly completed, and the increasing of the stamp weight is comparatively simple. The Homestake's new machinery at Lead includes a steam-driven electric-generating station with a maximum capacity of 4000 kva., which will, working in step with the hydro-electric plants of the company at Spearfish and Englewood, furnish sufficient power at all times of the year to drive all of the company's machinery except the hoisting-engines, which will continue to be operated by steam-power.

Good progress is being made by the Wasp No. 2 company in installing concentrating machines to treat low-grade wolframite ores, that have accumulated during several months of hand sorting of high-grade material, which has gone direct to the market. It is estimated that the dump contains $100,000 net of the tungsten ore. Production continues; 30 tons was shipped this month, realizing over $1800 per ton. A dividend of 5c. per share was declared on the 15th; next month's payments will probably be larger, as the concentrator should be working and returning profits by that time.

MELBOURNE, AUSTRALIA

Condition of the Metal Industry in Australia.

The metal trade of Australia is being welded into fresh form by the hands of the Commonwealth Attorney General and Prime Minister (Mr. W. M. Hughes). This Welshman is as vigorous and as daring a personality as is his countryman, Lloyd George. His career is typical of what can happen to a man with brains and strength of purpose in a democratic community like Australia. In the lowest walk of life at first, he associated with the wharf-laborers union, where his command of language and general capacity soon won for him the secretaryship of that organization, and next gave him a seat as the representative of Labor in the Legislature of New South Wales. There he sharpened his wits, broadened his ideas, and developed his brain by qualifying himself for the profession of a barrister. That achieved he stepped into the Federal Parliament as one of the two brainiest men in Labor ranks. The temporary victory of his party a few years since yielded him his first taste of office. The wholesale defeat of the Liberal party at the start of the War put him as second in control in the Government of the Commonwealth. Now the retirement of his old chief, Andrew Fisher, to take up the representation of Australia in London, furnishes Attorney-General Hughes with the most coveted position in Australia, that of Prime Minister.

This preliminary is necessary to explain the position of the metal market in Australia. Prior to the War, the great German houses of the Mertons, Hirsch, and Beer Sondheimer, with lights of less magnitude, had worked their way into the metal trade of Australia. That trade, on the face of it, represented annually from £12,000,000 to £14,000,000. The chief prizes originally were the handling, treatment, and subsequent sale of the lead concentrate of the great silver-lead district of Broken Hill. Then, as the flotation process developed there was added the output of zinc concentrate. In connection with this trade, Henry R. Merton & Co. controlled the organization known as the Australian Metal Corporation; in zinc came Beer Sondheimer & Co. Both these firms also were interested in lead and copper, but Aron Hirsch & Sohn was the biggest firm operating in the latter metal. The most solidly established house was the Merton organization, for it had the wealth of the Metallgesellschaft at its back. Its strength was such that it induced the Broken Hill Proprietary Co. to join the Lead Convention, and it had a large hand in creating the Zinc Convention, both of which fell to pieces when hostilities began. Owing to under-quoting, and to the gradual exhaustion of its mine, the Broken Hill Proprietary Co. had ceased to be the prominent figure it once was in the metal market save in the Far East. Owing to the high price of labor and other reasons that need not be detailed it could not afford to quote so low a returning charge as the German metal-buyer. Thus it lost the smelting of the output of some of the most important of the Broken Hill mines. As its ore reserves became depleted, a rival group that had let the product of their mines go abroad decided to get the control of the field. To do this they had either to buy the smelters at Port Pirie of the Broken Hill Proprietary Co. or start new works of their own. An attempt at purchase made some three years ago failed. The War changed everything, and as the Proprietary Co. was hard at work establishing large iron and steel works at Newcastle, New South Wales, what previously was impossible became possible. The group was enabled to buy a two-thirds interest in the Port Pirie works, on behalf of the North and the South Broken Hill companies, the Proprietary Co. retaining the remaining third interest. Since then other mines have joined the new organization, whose aim seems to be to control the bulk of the lead, silver, and zinc output of Broken Hill. It is avowed that this is to be done on a co-operative basis, that is, that the one aim of the promoters is the advancement of the interests of the shareholders of the affiliated companies. As the new central organization has a 50-year contract for the lead output of the leading companies, to its smelters will go the lead concentrate of Broken Hill for treatment. Germany therefore by one stroke seems to have been cut out of any future participation in the lead industry. The position is that the country has, in the Associated Broken Hill Smelters Co., an organization that controls the greater part of the lead output of Broken Hill. As to copper, the Electrolytic Company working at Port Kembla, in New South Wales, was owned mainly by the Mount Morgan Company and by Aron Hirsch interests. Here London influences, owing to a large investment in Mount Morgan shares, came into play. These were in touch with interests that dominated several mines in the copper region around Cloncurry in northern Queensland. So here was the basis of a second combination of the elements likely to cohere, although the Mt. Lyell and the Wallaroo and Moonta mines could not be brought into line unless they cared to do so. The tin smelting industry was represented by three concerns, of which the leader was the Mt. Bischoff in Tasmania. Their smelting charges, however, were such that a great deal of tin ore was sent from Australia to the Malay Peninsula to be treated and sold there. As for iron, the only concern of any size to tackle the problem of turning the resources of the Commonwealth to account was the Broken Hill Proprietary Co. at Newcastle. Antimony, wolfram, molybdenum, and other of the rarer minerals were all exported to Germany or went through German agents to different parts of the world.

All this trade in the export of lead and zinc concentrate was thrown into confusion on the outbreak of the War. A number of mines had to close down for a while, and others, like those at Broken Hill, could only work intermittently. The Broken Hill Proprietary came to the aid of the South Broken Hill and North Broken Hill mines by smelting for them at bare cost, but the mines could not make deliveries. Before long, however, the presence of Mr. Hughes began to be felt. He raided certain offices and the premises of firms connected with the metal trade. Following this he denounced as un-British and

undesirable the hold foreigners had on the metal trade of Australia. Next he set to work to smash certain trade connections with German buyers. The War had caused a suspension of all buying contracts. This was not sufficient for the doughty little Welshman. He demanded that there should be no dealing with firms or corporations that though British from the point of domicile were in fact German-controlled. His attitude in this respect went far ahead of what was done in Great Britain, but it had popular opinion behind it. Finally he passed legislation permitting companies or firms having contracts with German firms to annul them. Of course, where the companies were domiciled in Great Britain and the contracts signed there, he could not interpose. Still, his policy has had widespread support there, though as yet the British authorities have declined to follow Mr. Hughes' initiative. In Australia the controllers of a number of the mines were at first resentful and perhaps contemptuous. They had had the control of their properties so long under State law and under peace conditions that they could not understand being rounded up, as was being done by the Federal Attorney-General. A most remarkable pledge was exacted from the Broken Hill Proprietary Co., not to deal through the Merton houses in London. When certain people associated with the Mt. Morgan property applied for permission to act as agents for that firm. Hughes made them the subject of biting criticism. While doing this, he formulated the idea of establishing a metal exchange to handle the metal output of the country. Now that organization is at work. The reason it was constituted was to prevent powerful interests connected with the mines from shutting out locally established agents of British and Colonial houses from having the right to buy and sell metals in an open market. To ensure the elimination of the foreign element, transactions have to be carried out through the Exchange. If that is not done the Executive has to be satisfied that exports are intended for purely British consumers, for the Allies, or for approved firms in neutral countries. In short, the export of metals now is under State control.

Nor is this all: The aim of the little Welshman is to destroy the grip of the German on the Australian metal trade forever. He hopes to achieve that not only by the use of the legislative power at his disposal—a power that the British Parliament cannot touch unless it interferes with Australian self-government—but by granting assistance to industry here to establish manufactures out of the raw products hitherto sent abroad. One of his grounds of complaint in respect to the Electrolytic Company, referred to above, was that it had not responded to his request to promote a scheme for using the refined copper in manufacture. Here again Hughes is in accord with public sentiment, for this country has had forced upon it by the dislocation of trade at the outbreak of the War—the necessity for being self-contained in that respect. Still, it isn't clear that with hostilities at an end and with Australia a self-governing country, that the great markets hitherto utilized in Germany and elsewhere can be ignored. The population of the country is too sparse to allow of that, but it is certain that the 'made in Australia' call will be heard in a more incisive tone than ever. State regulation to enforce the policy initiated by Hughes will also be an accepted canon in public life. Lead and copper have been found to be easy to control so far, but it is different with zinc ore and concentrate. The quantity of ore carrying zinc in profitable quantity is not sufficient to justify, without heavy State backing, the outlay of capital necessary to enable zinc-distillation plants to be erected in Australia. Under considerable pressure, however, it now appears as if the Attorney-General is succeeding in getting the British authorities to co-operate in putting up works in England to which the Australian output shall go. This will meet national sentiment though it may clash with the re-opening of works in Belgium, to which hitherto, under German direction, our zinc concentrate has gone in vast quantities. As regards iron and steel, the Broken Hill Proprietary has established its works at Newcastle. There has never been a hitch over the enterprise. This has been due, first of all, to the persistence of the general manager, G. D. Delprat. American experts secured by him have built a steel plant at Newcastle that is second to none in efficiency. Australia now has started on the road to becoming practically independent of outside sources of supply of pig-iron and steel. It can be taken for granted that the State will not allow this iron and steel manufactory to suffer by dumping tactics. Already its usefulness in defense is being illustrated by the fact that the company is producing steel for the manufacture of munitions and that its output is wanted by makers throughout the Commonwealth. As Australia produces a fair proportion of the world's yield of wolfram and molybdenum, these minerals are available for use as alloys, though at present they, as well as antimony, are commandeered for the War Department.

The trade in tin ore is also likely to be regulated. A good deal of the ore sent hence to the Malay Settlements to be smelted will, if the ideas of the Attorney-General be adopted, be treated in Australia. It is hoped that the Broken Hill Proprietary will be able to utilize some of this tin in making tin-plate, just as the wish exists that, with zinc available, it shall engage in the manufacture of galvanized iron. Protection would be accorded, if necessary, and in all probability a leaf would be taken out of the German book in the matter of granting a big subsidy for the establishment of these industries. In conclusion, the broad fact is that the whole metal export trade of Australia is today under Federal control and direction. That control aims at the destruction of German pre-War connections with the metal and mining industries of Australia, and to make Australia more self-contained.

WASHINGTON, D. C.

Mining Law Revision.

During the meeting held at the Smithsonian Institution here, on December 16 (three sessions), the Mining and Metallurgical Society of America took a decided stand in relation to the appointment, by authority of Congress, of a commission to codify the mining laws of the country, and at the same time that a permanent committee of mining law revision would also be established, to consist of 15 members. The meeting was attended by 125 registered delegates, other mining institutions, etc., collaborating with the Society. The presiding officer over the first session was Carl Scholz, president of the American Mining Congress. He made a felicitous address; also one by Franklin K. Lane, Secretary of the Interior. Committees were appointed, that on resolutions being headed by Horace V. Winchell. Six resolutions were adopted, one being that the mining law be revised as a whole, not piecemeal. The resolutions were not adopted without discussion and attempts to amend them. It was proposed that the resolutions bearing on the codification commission be made to include Alaska, but it was shown that this Territory had mining laws of its own, independent of the United States. R. Macbeth of Idaho protested against any officer of the United States government being included in the commission. He was seconded by E. P. Smith of the same State. J. Parke Channing, as a conservationist, gently took issue with Mr. Macbeth; also Chambers Kellar, of South Dakota, and Edmund B. Kirby. The Macbeth amendment was lost by a considerable vote. The evening session was presided over by W. R. Ingalls of the M. & M. Society, succeeding W. L. Saunders, of the A. I. M. E., who presided in the afternoon. Among those in the audience were Senator Myers of Montana, and ex-Senator Clark from that State. Horace V. Winchell read a thoroughly prepared paper on mining conditions with respect to the laws, and Senator Thomas of Colorado made an address also on mining law conditions. He was followed by Senator Walsh of Montana in an elaborate paper.

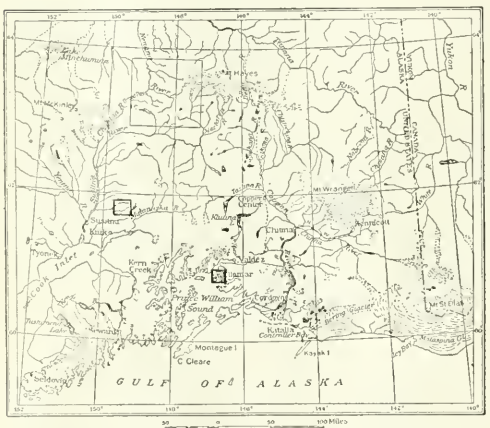
The U. S. Bureau of Mining, in charge of Van H. Manning, assisted the visitors in many ways.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Three interesting bulletins, No. 605, 607, and 608, have recently been issued by the U. S. Geological Survey. They are 'The Ellamar District, Alaska,' by S. R. Capps and B. L. Johnson; 'The Willow Creek District, Alaska,' by S. R. Capps,



PART OF ALASKA. THE AREAS WITHIN THE SQUARES ARE THOSE DESCRIBED IN THE SURVEY BULLETINS MENTIONED.

and 'The Broad Pass Region, Alaska,' by Fred H. Moffit, and Joseph E. Pogue. The situation, climate, geology, ore deposits, and details of mines being operated are given.

Charting the Kuskokwim river in Alaska has been completed by the U. S. Coast and Geodetic Survey during the past season. Among the rivers of Alaska, the Kuskokwim is second only to the Yukon in size, but on account of the large area of hitherto uncharted mud-flats at the river's mouth, it has been visited by only two or three small steamers during the year. The channel through these flats has been charted now. As a supplement to the coast work, a reconnaissance survey was made inland from Bethel, the head of deep-water navigation. By the use of the steamer *Yukon* this was carried up-stream 550 miles to McGrath, the main settlement on the upper river. Earlier maps of the river were found in some places to be as much as 50 miles in error.

JUNEAU

On account of the lower grade of ore mined at the Perseverance mine, the Alaska Gastineau company has reduced the output from 6000 to 4000 tons daily. This raised the value from $1 to $1.40 per ton. Plans have been devised to remove the 'horse' of schist that was the cause of the lowering of the grade.

KETCHIKAN

The geology of Gravina island, just across a narrow channel from Ketchikan, is discussed by Philip S. Smith in *Professional Paper* 95-H. of the U. S. Geological Survey. Whether commercial ores exist is not mentioned.

FAIRBANKS

According to the *Fairbanks Weekly Times*, which published the following table prepared by George Hutchinson, cashier of the First National bank, with the assistance of the officers of the American Bank of Alaska, and with suggestions from the agent of the Wells Fargo Express Co., the gold production of the Fairbanks district for the season 1915 was as follows:

Cleary and tributaries and Chatanika district	$ 667,000
Fairbanks creek and tributaries	262,000
Pedro and tributaries	327,000
Goldstream and tributaries	321,000
Little Eldorado	65,000
Dome	268,000
Vault	106,000
Ester	380,000
Other creeks in Fairbanks region	40,000
Placer production	$2,436,000
Quartz production	250,000
Total Fairbanks region	$2,686,000
Hot Springs	600,000
Tenderfoot	72,000
Tolovana	60,000
Outlying districts	43,000
	$3,461,000
Antimony, approximately 1000 tons	150,000
Total production	$3,611,000

The output is larger than in the two previous seasons. Some of the districts promise well for the future. The Tolovana output was made under unfavorable circumstances. The yield from quartz was lower, but next year it should be larger.

The mortgager of the Newsboy quartz mine, Mrs. A. E. Golden, has brought suit to foreclose on the property. There is $20,021 interest, costs, and fees due. The plant includes a boiler, compressor, crusher, five-stamp Joshua Hendy mill, engine, etc. A good deal of work has been done, and prospects are considered encouraging.

According to recent arrivals at Fairbanks there is considerable winter work being done in the Hot Springs, Koyukuk, and Ruby districts. Prospects are considered promising.

NOME

The deputy-collector of customs at Nome, R. W. J. Reed, has given out the following data regarding the navigation season of 1915:

Ocean vessels arrived, coastwise	40
Net tonnage	65,195
Ocean vessels departed, coastwise	40
Net tonnage	68,047
Arrivals from foreign ports	13
Net tonnage	5,045
Departures for foreign ports	15
Net tonnage	5,593
Freight received from United States ports:	
General merchandise, tons	13,910
Fuel oil, crude, tons	1,029
Coal, domestic, tons	3,214

Lumber, feet, b. m.	1,070,469
Live stock, head	46
Freight shipped to United States ports:	
General merchandise, tons	1,872
Placer tin, tons,	157
Antimony ore, tons	132
Gold dust and bullion shipped:	
Through Customs house, 151,567 oz., value	$2,796,952
Merchandise received from foreign ports:	
Value of free imports	$124,408
Value of dutiable imports	2,916
Foreign coal, tons	1,185
Passenger movements:	
Arrived from United States ports at Nome	1,604
Arrived from United States ports via Nome for St. Michael	183
Arrived from foreign ports	2
Departed for United States ports from Nome	1,402
Departed for United States ports via Nome from St. Michael	506
Departed for foreign ports from Nome	2

ARIZONA

In Bulletin No. 6 of the State Bureau of Mines, Charles F. Willis briefly describes the present condition of mining and industrial progress in the State. Bulletin No. 8, by P. E. Joseph, is on asbestos. The asbestos of Arizona is of excellent quality, and is unique in occurrence in that it is found as chrysotile in cross-fibre veins with serpentine in limestone. The principal deposits are in the Grand Canyon of the Colorado and on Ash creek, 40 miles from Globe. At the latter place, the new asbestos mill of Fisk and Snell, designed by T. Torrey of Canada, is producing one ton of fibre daily.

Cochise County

The most important new work under way in the Bisbee district is concreting the Copper Queen company's Sacramento shaft. Three hundred feet is finished, the rate being 10 ft. each three days. The fire in the Lowell ground is under control, and isolated by bulkheading. A good body of sulphide ore was cut recently at 700 ft. of the Spray shaft. A new hoist is being erected at the White Tail Deer lease.

Work continues at a big pace at the Calumet & Arizona and Shattuck mines.

Gila County

Two electric pumps on No. 18 level of the Old Dominion are lifting a little more than 6,000,000 gal. per day. The mine is producing 1000 tons of ore daily, mostly from No. 12, 14, and 16 levels. The mill is treating 700 tons per day. An M. S. flotation machine is treating the slime; coal tar is used, coming in tank-cars. Concentrate is thickened by a Dorr machine, and dried on an Oliver filter. Three blast-furnaces are working on company ore and concentrate, and custom ore. New economizers are being installed at the power-plant.

The Irene of Globe Mining Co. is starting to grade for a 50-ton mill at its silver-lead-zinc mine. James A. Fleming is president.

During November the Inspiration mill treated 180,000 tons of ore. The first unit of the second half of the plant is in operation. The automatic hoists at the main shafts are working well. Most of the ore comes from the Joe Bush orebody at No. 4 level. New concrete assay and engineering offices are nearly complete.

A 300-ton test-mill is being erected at the Miami mine, to be ready early in January. This will treat experimentally, also commercially, the low-grade ores.

Owing to a rush of ground from a stope above the 300-ft. level of the Gibson mine, W. ('Tip') Henderson, one of the owners, was killed. Beck, Gibson, and Henderson bought this mine in 1901 for $1000. In 10 years they produced $1,800,000, and since then $250,000, mostly by lessees.

Yavapai County

The old Blue Duck mines in the Hassayampa district will probably be re-opened by Cleveland, Ohio, people, Judge T. H. Bushness being one of them. The ore yielded exceptionally high in silver.

The mine of G. Thompson, in the Tule Creek tungsten area, is producing good ore in shallow shafts.

Like the old Tip Top mine, the Pearl silver mine is said to contain wolfram ore. Other claims have good tungsten prospects.

CALIFORNIA

The State Industrial Accident Commission has issued 'Mine Safety Rules,' of 123 pages, also 'Miscellaneous Rules for Underground Men' of 7 pages, which are effective on January 1, 1916. The latter is to be published in Spanish, Italian, and Croatian (all Slavic dialects, such as Bohemian, Polish, Serbian, and Slavonian are included in Croatian). The mine-safety rules were drafted by A. P. Anderson, G. W. Metcalf, N. S. Kelsey, and Arthur B. Foote, representing the California Metal Producers' Association; James Giambruno, J. C. Williams, and A. M. Arandall for the mine employees, and H. M. Wolfin for the Commission. Under Section 5 artificial breathing apparatus is discussed, but this is not effective until April 1. The publication contains all points coming under safety practice. Section 2, 'Reports to Inspector,' the U. S. Bureau of Mines will send forms to California mines requesting data for 1915. The request will be made that these forms be filled out and mailed to the Commission. If operators and superintendents will see that this request is complied with within a reasonable time, no request will be made by the Commission for additional annual reports to the inspector for 1915. The index of 21 pages is very complete. 'General Safety Orders,' of 15 pages, has also been issued. They are effective on January 1. The names of the committeemen responsible for the orders are given. Safety-first accomplishments (the work done by the Commission) occupy two pages.

Amador County

Following is the preliminary report of the output and expenditure of the Plymouth Consolidated for November:

Ore milled, tons	10,000
Value of gold	$46,949
Working expenses	24,184
Development charges	4,640
Surplus	$18,125
Capital expenditure	204

The Sutter Creek Mining Co. has acquired the Poundstone mine at Sutter Creek, once known as the East Eureka. It is well equipped, including an electric hoist, compressor, and 20-stamp mill.

Two men were killed in the Kennedy mine on December 20. A timber-boss, W. T. Harvey, walking down the ladderway of the shaft, slipped off and fell on top of an Italian miner who was riding on a skip, both then falling to the bottom of the shaft, 3900 ft. deep.

The South Eureka company treated 12,050 tons of ore in November, yielding $51,002, and a profit of $14,975. A dividend of 5c. per share has been declared, equal to $30,988. The company employs 250 men. It has commenced exploration on the lower levels of the Oneida mine, nearby.

At the Central Eureka mine 30 stamps are crushing ore from the 2800, 3000, 3100, and 3200-ft. levels. J. E. Davis is in charge of 100 men.

Nevada County

In order to loosen a long bank of gravel at the Brandy City Gravel Mines, in charge of G. F. Taylor, 22,000 lb. of powder is to be set off. Twenty men are employed.

The Golden Center company has declared dividend No. 2 of 4c. per share, equal to $11,500. The main shaft is down 833 ft. Ore reserves are sufficient for an increased mill capacity.

Placer County

(Special Correspondence.)—Owners of the Grey Eagle mine, four miles from Forest Hill, have ordered two Joshua Hendy batteries of three stamps each.

The third unit of three stamps at the Excelsior mill is nearly ready for crushing. The nine stamps will be able to reduce 150 mine-cars of ore daily.

Forest Hill, December 17.

The Valley View mine, near Lincoln, has been bonded to the Guggenheim interests for $25,000. This firm is operating the Dairy Farm mine near Sheridan.

Plumas County

River claims (Feather river) near Rich Bar, are to be worked next year by Henry Finch of Seattle, who proposes to use a clam-shell dredge, suction pumps, and diving apparatus.

Shasta County

It is reported that 40% dynamite has advanced $90 per ton during the past two weeks. This is serious for the Mountain Copper Co., which uses 17 tons a month at its Iron Mountain mine. The Mammoth company uses more. Forty and sixty per cent dynamite cost $330 and $420 per ton respectively.

Sierra County

Owing to a heavy snowfall the transmission-line from Pike City to Alleghany was broken, resulting in the mines, plants, and the towns of Alleghany and Forest City being without light and power.

The Eastern and Western Cross claims of Bovee Bros. have been bonded to P. O. Jackson of Iowa for $50,000.

Siskiyou County

Manganese claims near Greenview are likely to be sold to San Francisco people.

Trinity County

Gravel near Hayfork is being tested by a Keystone drill for San Francisco people.——The Heurtevant ranches below Junction City are said to be sold to a New York syndicate, which may erect a dredge.

On account of the winter, work has been suspended at the Trinity Asbestos Mining Co.'s property at Castella. A 100-ton rock-crushing plant, 25,000-ft. sawmill, and 12 miles of 6% grade road were constructed, the latter costing $45,000. H. T. Mecum of Oakland is president.

Tulare County

Two miles from Lindsay a rich magnesite deposit has been discovered.

COLORADO

Clear Creek County

According to the superintendent of the Big Five tunnel, D. A. Barry, the adit is to be extended another 1000 ft., making 10,053 ft. It will be driven by contract. The heading is within 250 ft. of the Gilpin County line. The new work will go under the south slope of Pewabic mountain. Beyond and along its course are most of the big mines of Russell gulch. A good deal is expected from the extension in the way of developments.

San Juan County

Experiments in flotation are under way at the Sunnyside mill at Silverton, in charge of James H. Hyde and others.—— The Contention mill is being repaired. Flotation will probably be used.——Work is to be resumed at the North Star mine on Sultan mountain.——The tungsten mines on Cement creek are sending ore to the local mill.——Developments at the Buffalo Boy are very satisfactory, the shoot being over 1000 ft. long. Sinking is underway.

San Miguel County

During November the Tomboy mill treated 12,000 tons of ore, yielding $42,000 of bullion, and $44,500 of concentrate, a total of $86,500. The profit was $28,400.

IDAHO

Boise County

In the Deadwood district the Hall Interstate Mining Co. has a fairly developed high-grade lead-silver mine. It requires a 12-mile wagon-road to allow shipments to be made.

Boundary County

A No. 45 Bucyrus steam-shovel is to be used by the Idaho Gold & Ruby Mining Co. in digging a ditch for hydraulicking at Lenia. Sluicing is to commence in July next. Sixty men are employed. The ditch is about half finished, excavation started in November 1914. The canal, 4¼ miles long, 12 ft. wide at the bottom, 30 ft. at the water-line, and 60 ft. at the top, will carry an average of 2000 second-feet of water, adequate for maximum operations. It will be supplied from Boulder creek, a tributary of the Kootenai river, and when completed will represent an expenditure of not less than $100,000, according to the president, John L. Schnatterly.

Shoshone County (Coeur d'Alene)

A well-defined lode of quartz, iron, and galena, 8 to 20 ft. wide, has been traced by trenches for 2000 ft. in the Virginia claim of the Red Monarch Consolidated in the Nine-Mile district. An adit has been started on the orebody. Diamond-drilling on the Red fraction has disproved the theory of faulting. A compressor-plant and boarding-house are being erected. Conrad Wolfle of Spokane is president.

In the Murray district is the old Golden Chest property of large area, where work has been resumed after eight years. About three miles of openings have been made in the past. A stamp-mill worked for many years. The Klondike ore-shoot yielded $250 per ton in lead, silver, and gold, and large quantities of tungsten ore were discarded. Samuel Green of New York intends to operate the mine mostly for tungsten ore.

The Success company in the Nine-Mile district made a profit of $70,000 in November. On December 23, 3c. per share was paid, equal to $45,000. This makes $555,000 for 1915, and $1,830,000 to date.

At a vertical depth of 325 ft., and at a point 1410 ft. from the portal of the adit, the vein in the Richmond mine at Adair has been cut. The shoot in the upper levels is 500 ft. long, from which six carloads of ore returned $4600 net.

For $250,000 the Rex Consolidated company has secured an option on control of the Black Bear Consolidated stock. Black Bear ore will be treated at the Rex mill at Nine-mile, now used by the Tamarack & Custer.

Well-known mining people, constituting the Northwestern Mines Development Co., have purchased property in the Keller-Nespelen district for $150,000. The ores contain copper, gold, silver, and zinc. W. E. Malm of Wallace is general manager.

MICHIGAN

The Copper Country

The *Boston News Bureau* has calculated the following output and profits of the Calumet & Hecla and its subsidiaries in 1915:

	Pounds.	Net.	C. & H. equity.
Calumet & Hecla	65,000,000	$5,500,000	$5,500,000
Ahmeek	20,000,000	2,200,000	1,100,000
Osceola	18,000,000	1,400,000	450,000
Allouez	10,500,000	950,000	380,000
Isle Royale	10,000,000	550,000	115,000
Superior	4,000,000	270,000	135,000
Centennial	2,500,000	150,000	70,000
Total	130,000,000	$11,020,000	$7,750,000
Per share on C. & H.			77.50

Calumet & Hecla's receipts from subsidiary dividends in 1915 will have been $862,776, which, with its own profits would make $6,300,000, or $63 per share against the $77.50 calculated.

(Special Correspondence.)—The third of the large furnaces

for the Calumet & Hecla smelting-plant at Hubbell is now being constructed; work will be continued during the winter, making this a valuable addition to the plant. The new furnace will have a capacity of 150,000 lb., and will have electric equipment for loading and dumping. It is modelled after No. 20 and No. 21, each of which has a similar capacity. In addition to these three large furnaces the plant at Hubbell has 15 smaller ones, each with a capacity of 30,000 lb. The Calumet & Hecla smelting and refining plants at Hubbell now have a pay-roll of 500 men, twice what it was a year ago.

Ahmeek's mill now is operating six stamps and crushing close to an average of 100,000 tons of copper ore each month, so that the production is now at the rate of better than 25,000,000 lb. per year.

Sales of metal from the Quincy have been made four months in advance.

Houghton, December 10.

MISSOURI

Jasper County

It was hoped that the zinc-lead region would produce a total value of $25,000,000 this year, but this will probably not be attained, as for 50 weeks the amount is $24,003,765, and the present price of ore is rather too low to make up the former figure. Joplin and the Webb City-Carterville districts have produced as much as the whole region in 1914.

MONTANA

Cascade County

(Special Correspondence.)—The continued demand and future of copper is said to be responsible for changes made in the concentrating work being done in the Boston & Montana reduction department at Great Falls.

It was understood that work in the mill here would be discontinued on January 15, 1916, concentrating to be done at Anaconda, and the concentrate shipped here for treatment. While no official announcement has been made it is understood that there will be no shut-down, and the plant will continue operating for an indefinite period. The concentrator at present employs about 100 men.

Great Falls, December 15.

Silverbow County

The president of the Butte & Zenith company, I. Freimuth, is at Butte from Duluth, and work is soon to be resumed at the mine in charge of W. Gibson. The ground has been opened to 670 ft., while the plant is equal to 1500 ft. The shaft is to be sunk to 1000 ft. The property is four miles west of Butte, near some other good claims.

The new flotation-plant at the East Butte has started work.

NEVADA

Esmeralda County

During November the Jumbo Extension shipped 2655 tons of ore worth $70,000, giving an estimated profit of $25,000. Lower-grade ore had to be mined, and was included in the shipments, reducing the grade. It was more economical to extract this ore than to leave it for a later period. The mine is in fine condition. Stopes 541 and 546 are giving assays from $50 to $200 per ton over 4 to 7 ft. Owing to a connection with the Velvet shaft at 790 ft. better ventilation has resulted. The output for 14 months totals 24,209 tons worth $1,072,912, of which $612,853 was net; dividends amounted to $493,410.

The Atlanta is producing three cars of ore per week from the 1580 and 1620-ft. levels.

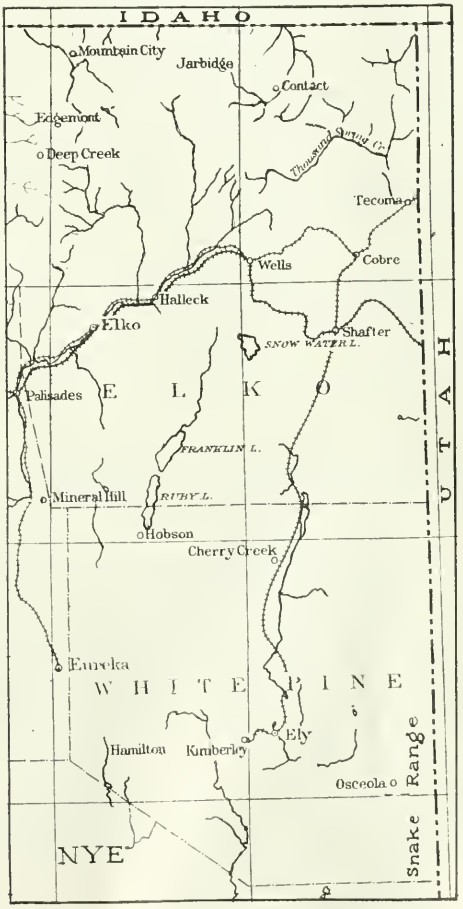
The ore-channel opened in workings above the Simmerone's 100-ft. level has been reached by the drift at that depth. Work is to be started at 250 feet.

Development at the old Tip Top mine is said to be highly encouraging. Reno people are mostly interested.

At a depth of 170 ft. in the Pioneer Consolidated, 50 miles south of Goldfield, a face of ore 11 by 12 ft. has been exposed, assaying in sections from $3.20 to $226 per ton. This is considered very important. Other parts of the mine are opening well.

White Pine County

The Snake Range district is attracting many prospectors and others. Owing to a recent discovery by E. Millick and Jasper Fox, at the southern end of the range, 25 miles or so south of Osceola, the scheelite and hübnerite belt now extends



PART OF NEVADA. THE TUNGSTEN DEPOSITS ARE IN THE SOUTHEAST OF WHITE PINE COUNTY.

for a length of 70 miles. Between Minerva and north of Red Hills there are three mills in operation, another is to be erected at Scheelite. About 300 men are employed in the region in various ways.

The Nevada Consolidated company's November *Safety First* shows that 11 accidents at Copper Flat, 25 at the Ruth mine, 2 at the mill, and 6 at the smelter, resulted in a total loss of time to the men of 356 days.

All the tungsten camps in the east part of the county are busy. Four mills are producing concentrate. New developments are frequently reported in the Snake Range area.

Molybdenite has been found by A. Munter in the north-east

corner of the county. The ore contains 7% metal. The deposit was located 10 years ago, but was not developed.

HUMBOLDT COUNTY

At Rochester the Friedman adit is in 1500 ft. At 1470 ft. a raise is going up to connect with winze 301, and the east vein will be cut 340 ft. below the bottom of the winze.

More than $100,000 of gold and silver bullion per month from the mines in the Rochester and Seven Troughs districts in this county in excess of 1914 monthly shipments, are passing through the banks of Lovelock.

In digging a hole at Antelope Springs, 25 miles from Lovelock, a badger threw out rich antimony float. This was noticed by J. H. Caustin, who has found a five-foot lode containing up to 60% antimony. Forty feet has been exposed. Ten tons was extracted in one day.

The Nevada Packard mill is said to be extracting 98% of the silver and gold-content of the ore, 112 tons being treated daily.

Some remarkable cinnabar has been opened in Dry gulch, in the Unionville district, by Alvin Chester. A wagon-load from 25 ft. depth returned $742.

LINCOLN COUNTY

The first unit, 50 tons, of the Amalgamated mill, at Pioche, is to be erected at once. Concentration by water and flotation are to be included.

The Prince Consolidated has acquired the Pioche King property.

The Bristol district is very busy. The California-Nevada and Tempest are shipping.

LYON COUNTY

In the suit of the Pacific Livestock Co. *v.* the Mason Valley Mines Co., in which the former tried to stop the operation of the smelter at Thompson, on account of alleged damage by fume, the appeal to the Supreme Court was dismissed.

NYE COUNTY

A circular from the Round Mountain Mining Co. states that from April 1 to September 30, inclusive, the revenue from 25,345 tons of ore was $145,162, or $5.73 per ton. Costs, including depreciation, were $4.39, leaving $1.34 per ton, or $33,852 profit. Hydraulicking 18,150 cu. yd. (part clean-up) gave $33,102, or $1.82 per yard. Costs were 49c. per yard, leaving $24,179 profit. The total profit was $58,031. The whole water supply and sluicing outfit cost $192,888. It has been paid for. The company has no debts. Cash on hand at the end of September was $7545.

Tonopah mines last week produced 9716 tons of ore worth $200,848.

For November the Belmont reports 12,503 tons treated for 217,777 oz. bullion, and $64,535 profit; the Tonopah M. Co., 12,200 tons of $15.44 ore, and $92,800 profit, and the Jim Butler 4407 tons for $18,949 profit.

STOREY COUNTY

Last week the Mexican mill shipped bullion worth $15,000, the result of treating ore from 2400 and 2500 ft. in the Union and Sierra Nevada. The plant is now treating 60 tons per day. ——Favorable formation is being driven on at 2700 ft. in the Ophir.——At Gold Hill, important work is under way at 1600 ft. in the Jacket-Crown Point-Belcher property. The mill is working full time.

NEW MEXICO

GRANT COUNTY

It is reported that the Burro Mountain mill will commence operations in January. Concentrate will be shipped to Douglas.

OREGON

JACKSON COUNTY

It is reported that molybdenite has been discovered in Ashland Creek canyon near Ashland. A local syndicate will develop the deposit.

SOUTH DAKOTA

LAWRENCE COUNTY

According to George V. Ayres in *The Pahasapa Quarterly* of the South Dakota School of Mines at Rapid City this county has now over 100 miles of the best highways in the State. From 1883 to 1911 the sum of $454,658 was spent on roads and bridges, with no satisfactory result; but the expenditure of $330,210 from July 1911 to July 1915 resulted in the above length of roads. These are of great benefit to the mining industry.

The *Lead Daily Call* of December 11 was a special large edition devoted to the district, including the principal mines and men.

The Homestake company has shipped a carload of wolfram from small shoots in the Hidden Fortune claims. No large deposit has been found.

UTAH

According to *The Salt Lake Tribune* Utah mines this year have produced 10,500,000 tons of ore valued at $60,000,000. This is an increase of 2,000,000 tons and $23,000,000. These valuations were carefully made on average metal prices. The metal output will be approximately 190,000 oz. gold, 13,000,000 oz. silver, 185,000,000 lb. copper, 220,000,000 lb. lead, and 23,000,000 lb. spelter. Bingham, the Cottonwoods, and Park City show large gains.

Transactions on the Salt Lake Stock Exchange during 11 months totaled 15,461,931 shares, valued at $3,388,875, compared with 3,387,020, worth $693,473, in the whole of 1914.

BOXELDER COUNTY

Net profits of the Lakeview Mining Co. in November were $31,000, from 19 cars of 32% zinc ore. The dividend was 2½c., equal to $12,500. S. S. Arentz is superintendent. The Promontory district is certainly busy, considering that it was unknown a year ago.

JUAB COUNTY

The coming year is expected to be a busy one in the Tintic district. It is probable that the Plutus and Godiva companies may consolidate for extensive development.

PIUTE COUNTY

'Recent Alunite Developments near Marysvale and Beaver, Utah,' is the title of Bulletin 620-K of the U. S. Geological Survey by G. F. Loughlin, from which the accompanying map is taken. In the PRESS of November 27 the potash question was discussed editorially. The character of the deposits and their value is described in an interesting manner. A plant at Marysvale is now producing 25 tons of potash per day from this mineral.

SALT LAKE COUNTY

A 100-ton sulphuric-acid plant is to be erected at the A. S. & R. smelter; it will take four months for construction.

SUMMIT COUNTY

Metals sold by the Silver King Consolidated from January to November, inclusive, were 567,541 oz. silver at 48.75c. per oz., and 6,827,684 lb. lead at 4.57c. per lb. The profit was $276,676.

CANADA

BRITISH COLUMBIA

Seven feet of zinc ore, with some lead, is being opened between No. 7 and 8 levels of the Standard mine at Silverton. At the east end of No. 710 stope there is 135 ft. of ore without a break.

The Hedley company, operating the Nickel Plate mine, has declared its 3% dividend, with an extra of 7 per cent.

Ontario

During November the Nipissing high and low-grade mills treated 125 and 6448 tons of ore respectively, yielding silver worth $164,846. The refinery shipped 531,096 oz., part being from custom treatment. Prospecting by hydraulicking was stopped, 111 acres being sluiced during the season. At No. 73 shaft, a raise from the first level to the surface, 80 ft., a 1½-in. vein was partly developed, assaying 2500 oz. per ton. Other veins, containing up to 3407 oz. per ton, were opened. Work on the Nipissing portion of the Cobalt Lake fault vein will be done through shaft No. 81, which is down 86 ft. Levels will be driven at 350 and 475 ft. Surface plant has been erected.

The Beaver Con. shaft is down 1234 ft. The diabase-keewatin contact occurs between 1600 and 1700 ft. The shaft will be sunk to this point. The mill is treating up to 150 tons daily. The company had at the end of November $122,674 cash, and 220,015 oz. silver in various stages. The company has commenced development of the Kirkland Lake Gold Mines property in the Kirkland Lake district.

Dividends paid by Cobalt, Porcupine, and Kirkland Lake companies are as follows, according to *The Northern Miner*:

	1915.	To date.
Beaver	$ 120,000	$ 590,000
Buffalo	.....	2,787,000
Caribou Cobalt (Drummond)	125,000	225,000
Casey Cobalt	.....	203,249
City of Cobalt	.....	139,321
Cobalt Central	.....	192,845
Cobalt Lake	.....	465,000
Cobalt Silver Queen	.....	315,000
Cobalt Townsite	.....	966,726
Coniagas	600,000	7,840,000
Crown Reserve	141,505	6,102,399
Foster	.....	45,774
Hudson Bay (Timiskaming and Hudson Bay)	.....	1,940,250
Kerr Lake (holding company)	450,000	5,970,000
LaRose (holding company)	412,122	6,591,983
McKinley-Darragh Sav.	269,723	4,606,751
Mining Corp. of Canada	259,375	518,750
Nipissing Mines Co. (holding Co.)	1,200,000	13,840,000
Right of Way Mines	.....	219,110
Right of Way Mining Co.	.....	324,643
Peterson Lake	126,095	252,191
Seneca Superior	335,218	981,212
Timiskaming	75,000	1,459,156
Trethewey	.....	1,061,998
Wettlaufer	.....	637,465
Private corporations	175,000	3,825,000
Total	$4,289,038	$62,100,823

Porcupine and Kirkland Lake:

	1915.	To date.
Hollinger Gold Mines	$1,560,000	$4,170,000
Dome Mines	400,000	400,000
Porcupine Crown Mines	240,000	420,000
Rea Mines	12,000	12,000
Tough Oakes Gold Mines	65,187	65,187
Total	$2,277,187	$5,067,187

During November the Alexo nickel mine shipped 1305 tons of ore to the smelter at Coniston. This was a record.

At Kowkash a contract has been let to sink a shaft 50 ft. at the King-Dodds claim. This will be the first serious development among the 440 claims staked in the district.

Yukon

No. 1 dredge of the Canadian Klondyke company stopped for the winter on November 28, beating all records for creek work, having worked 11 days longer than the season of 1914.

PERSONAL

Robert A. Kinzie is at Oatman.

B. L. Thane is here from Juneau.

George Macfarlane has returned from Burma to London.

G. D. Kislingbury left San Pedro on December 18 to return to Rosario, Mexico.

H. W. Turner has been examining quicksilver prospects in Monterey county.

Eugene B. Braden has returned from a month's visit in New York and Washington.

S. S. Clarke has been appointed superintendent for the St. Joseph Lead Co., at Leadwood, Missouri.

Richard Roelofs, general manager of the Cresson mine at Cripple Creek, has been visiting Oatman, Arizona.

Ralph E. H. Pomeroy, superintendent of the Steptoe Valley smelter, has been visiting Great Falls and Anaconda.

Edward T. McCarthy has returned from Russia to London, after inspecting the Spassky and Atbasar mines in Siberia.

P. O. Wells, consulting engineer for the Cerro de Pasco Mining Co. in Peru, is touring the Western copper districts.

George B. Holderer, manager of the Furlough Development Co., at Wickenburg, Arizona, will spend Christmas in New York.

Henry G. McClain has succeeded W. E. Tracy as superintendent for the Liberty Bell Gold Mining Co., at Telluride, Colorado.

L. W. Trumbull is now in the oil-fields of southern Illinois. He will be at the Raleigh, Washington, D. C., during the G. S. A. meeting.

Russell G. Wayland has been promoted from assistant superintendent to chief superintendent of the Alaska Treadwell group.

H. W. Hardinge has been awarded the John Scott medal, for the invention of his conical mill, by the Franklin Institute, Philadelphia.

T. Skewes-Saunders formerly assistant-manager of Las Dos Estrellas, at El Oro, Mexico, succeeds Andre P. Griffiths as general manager.

Chas. E. van Barneveld, Professor of Mining in the University of California, is visiting Washington during the Christmas vacation.

W. L. Cumings has returned home from a four months trip to Peru and Chile, where he made various examinations for the Bethlehem Steel Company.

L. H. Metzger, formerly with the Goldfield Consolidated, succeeds R. G. Wayland as assistant superintendent of the Alaska Treadwell group of mines.

L. G. Huntley of the firm of Johnson & Huntley, Pittsburg, recently returned from the Kansas and Oklahoma oilfields, and is at present engaged in professional work in West Virginia.

Philip R. Bradley has become general superintendent of the Alaska Juneau mine, retiring as superintendent of the Treadwell group, with which he will continue to be connected as consulting engineer.

J. C. Puttner, superintendent of the San Juanes Reduction Co., Lower California, Mexico, is returning to the property after three months in the States. The company operates south of the El Boleo, and has not been affected by the revolution.

George J. Maas, of Negaunee, Michigan, died December 2, aged 54. Besides being known for the Maas diamond-drill compass, he was a successful explorer for iron ore and a fee-holder of Michigan lands.

THE METAL MARKET

METAL PRICES.

San Francisco, December 22.

	Cents per pound.
Antimony	40
Electrolytic copper	20.75
Pig lead	5.65— 5.85
Quicksilver (per flask)	$130
Spelter	20
Tin	40
Zinc-dust, 100-kg. zinc-lined cases	30

ORE PRICES

San Francisco, December 22.

Antimony: market weaker; 50% product, per unit	$ 2
Chrome: 52% chromic oxide and 2% silica per ton	12
Magnesite: plastic, no iron and lime, calcined, per ton	55
Magnesite: refractory, up to 7% iron, calcined, per ton	30-35
Manganese, 50% metal, 8% silica, per ton, f.o.b. cars, S. F.	12
Tungsten: minimum 65% WO_3, per unit for spot	$35—45

New York, December 17.

Manganese: For Brazilian ore, such as is used in the manufacture of 80% ferro-manganese, 44c. per unit has been paid. Plenty of Brazilian ore is to be had provided ships can be found for its transportation. One steamer was offered at a rate that would have made the cost of the ore 64c. per unit. The U. S. Steel Corporation recently contracted for 85,000 tons of Brazilian manganese ore. Shipping conditions are such that Indian ore is practically unobtainable.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 23.—There is renewed activity in copper, and it is steadily rising; lead is quiet but firm; prompt zinc is scarce, the market is firm.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 16	55.12	Nov. 10	50.02

June	56.43	49.03	Dec.	49.27	....

The undertone continues good, due to large sales to Europe coming on a market bare of supplies. Export of silver to India and China from London to December 1 totaled £3,559,000, against £4,721,500 in that period of last year. On December 18 a shipment to China from San Francisco was valued at $716,180, equal to about 1,300,000 oz. According to J. S. H. Umstead, in 'Financial America,' the world is facing a deficit in silver production of 50,000,000 oz., with no new field in sight.

Exports during the week ended December 4 totaled 20,332,169 lb., valued at $3,802,107. Of this, England absorbed 5,706,520; France, 7,871,554, and Russia, 2,581,374 lb. Imports amounted to 1,882,839 lb., worth $183,244. Chile sent 1,062,900, and Peru 247,973 pounds.

November returns include 6,000,000 lb. from Cerro de Pasco, and 4,000,000 lb. from Miami.

Phelps, Dodge & Co. paid $20 per share this year, against $14 in 1914. Granby Consolidated will pay $1.50 per share on February 1.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Ore prices at Joplin rose last week to $105, the lowest being $90 per ton for 60% product.

During November the Butte & Superior produced 16,451,000 lb. of spelter from 52,430 tons of ore. The estimated output in 1915 is 75,000 tons of metal, giving a profit of $9,000,000.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Tin is dull at 39 cents.

The new A. S. & R. tin smelter at Perth Amboy is to receive over 600 tons monthly of concentrate from the Cia. Estañifera de Llallagua, also some from the Cia. Minera de Oruro and mines near La Paz.

Eastern Metal Market

New York, December 17.

With domestic consumers satisfied for the present, the copper trade is principally concerned with the export situation. With its munition plants now running full blast it is probable that Great Britain will be a heavier buyer of ingot copper. Already this month, 21,809 tons has been exported. Zinc quotations took an upward turn when 15c. was touched, and the galvanizers commenced to buy. To the surprise of everyone the A. S. & R. Co. advanced its lead quotations on December 14, $3 per ton. The market had been dull and weak, and the trade can only ascribe the rise to export activity. It is reported that arrivals of tin will be restricted until Great Britain has accumulated a stock of about 4000 tons. Spot antimony continues scarce, and prices are firm. Aluminum is a trifle easier. In all the metals many buyers heretofore unknown to the trade are coming to the front. Practically all of them have war orders of one kind or another.

The exchange rate for the pound sterling was firm on December 16 at $4.72.

The pressure on the steel trade is reflected in the November report of the U. S. Steel Corporation, showing that its unfilled orders, as of November 30, had increased 1,024,037 tons as compared with October 31. The total on the books was 7,189,489. The increase was next to the largest on record. The mills continue to decline business, and prices are irregular. Iron ore for 1916 delivery has been active. Heavy sales have been made of both New York state and Lake Superior ores. The producers of the latter are much concerned over the shortage of mining labor, and the question is taking rank with the shortage of boats and the high freight-rates. Ore-shippers are buying Lake boats to insure the movement of their product. Pig-iron continues to climb.

ZINC

Some large inquiries have been before the trade, but prices have been more affected by London, and certain manipulative influences here than by demand. Sellers adopted the policy of declining to quote or give refusals, thereby working the consumers up to a state of excitement. The market moved rapidly from around 15c. per pound on December 9 to 17.50c. on the 15th. Then the market became easier. At the lower level mentioned some of the galvanizers took hold and bought freely, but their activity tapered off as prices advanced, and again their buying is at a standstill. It is estimated that not more than 50% of the galvanizing industry is active. Galvanized sheets, No. 28 gauge, are quoted at 4.75 to 5c. They have been offered a little more freely of late by makers who bought spelter on the declines.

Sheet-zinc, carload lots, f.o.b. mill, was unchanged on December 16, at 22c., 8% discount for cash. The London quotations for zinc have been erratic. On December 13 the quotation was £82 for prompt; £86 on the 14th; £93 on the 15th, and £90 on the 16th. Exports from December 1 to 18 totaled 4218 tons.

COPPER

With the requirements of domestic consumers practically filled for the time being, the market has reached a stage where it is extremely responsive to conditions at London; it sways with every rumor that comes along. The minimum quotation for electrolytic has been close to 17.50c., New York, since the last report, although the producers have adhered to 19.75 to 20c., 30 days, delivered. On December 15 second-hands withdrew from the market following reports that export-sales had been made at 20c., but 19.50c. was offered again on the following day. The London price touched £98 in the week, but on December 16 it declined to £97 10s. The importance of the London market, now that domestic buying has subsided, is emphasized by the fact that the exports in the first half of this month amounted to 19,996 tons. On December 17, the total was 21,809 tons. In this connection the interesting fact is pointed out that England now has her munition factories well organized, and from now on may be expected to buy more heavily of ingot copper. Some authorities assert that there will be a falling-off in exports of manufactured products, but it is not to be forgotten that contracts in hand here must be executed, also that deliveries on some of these contracts have not begun in earnest. Orders for many hundreds of tons of sheet-brass cannot find placement, and those who would go into the business of making this product are finding it difficult to obtain the necessary machinery. The following comparative statement of copper exports from the United States in 11 months of this year was compiled by C. Mayer, secretary of the New York Metal Exchange, in long tons:

	1915.	1914.
United Kingdom	69,280	80,175
France	83,699	56,150
Germany	.....	88,452
Holland	1,280	58,940
Belgium	.....	2,876
Austria	.....	13,809
Italy	39,551	23,607
Denmark	2,126	3,875
Norway and Sweden	17,091	6,909
Russia	17,921	125
China and Japan	119	1,890
Sundries	2,851	1,255
Total	233,918	338,063

LEAD

Large export sales, quietly negotiated, are held accountable for an advance of $3 per ton, or from 5.25 to 5.40c. per pound, New York, at a time when the domestic market was dull. Consumers were well supplied and second-hands were shading prices a few points when, to the surprise of all, the A. S. & R. Co., on December 14, announced the advance. Independents followed, but in the course of a few days they were again ready to sell at 2½ points under the new price. London has been strong. Exports from December 1 to 18 total 4985 tons.

TIN

The feature in tin is a report that exports from England will be curtailed until Great Britain has in store a stock of the metal sufficient to meet future contingencies, about 4000 tons. It is understood that at least a part embargo will be placed on the metal. Except on two or three days when fair quantities changed hands the market has been dull. Practically all of the business was in futures. The spot price on December 10 was 39c., on the 16th it was 39c., and the 17th, 40c. Arrivals up to the 17th totaled 3035 tons, and there was afloat on that day 5533 tons.

ANTIMONY

The quotation for spot antimony, Chinese and Japanese grades, was firm at 39c., duty paid, on December 16, but futures were easy because of anticipated arrivals.

ALUMINUM

Virgin metal, 99% pure is a little easier at 57 to 59c., with 98 to 99% at 56 to 58c. Substitutes are still being sought and this may have something to do with the easier quotations. The leading interest still declines to quote.

A New Two-Way Side-Dump Mine-Car

The accompanying illustration shows a new type of car worked entirely by hand, claimed by The Thomas B. Jeffrey

OPERATION OF THE NEW CAR.

Co., of Kenosha, Wisconsin, to do its work quicker than most power-dump bodies. The body is fitted to a Jeffrey quad truck, which is giving general satisfaction. No further description of the machine is necessary, the photograph showing how useful it should be around mines.

Drills and Lanterns

Among new electric apparatus, the Western Electric Co., in notes entitled 'Western Electric Developments in 1915,' describes the following:

A portable electric-drill and a portable electric-hammer have been placed on the market. The former is well-balanced, compact, and light. It will give the most efficient service in drilling and tapping work under the most exacting conditions. The motor will reverse readily at high or low speed. The switch, conveniently placed near the handle, makes it easy to reverse the motor when the drill sticks.

The electric-hammer is a sturdy, compact device that will produce uniformly strong blows at the rate of 1300 to 4000 per minute. It cannot be over-loaded, nor burn out. The hammer will do the work of a pneumatic drill at a 15% saving of power alone; over hand work, the saving is from 80% to 90%.

An electric lantern operated by dry battery has been placed on the market to meet the demand for a safe light that can be left burning anywhere without danger of fire. This lantern is made in two sizes, one giving a powerful light and making use of two dry batteries, and another, with a slightly less brilliant light, arranged for one battery only. A noteworthy feature is that turning the reflector lights the lantern, and moving it in the opposite direction extinguishes the light. Turning the reflector operates the switch which is wholly concealed, so that there are no moving parts on the outside of the lantern casing. A swinging bail is provided for convenience in carrying and for locking on the top. A rigid-slotted handle is also provided for hanging the lantern on a rail. The metal case is finished in automobile lamp black enamel. The light from this type of lantern will show an object 200 ft. away.

WANTED—Competent placer miner, familiar with hydraulicking pipe and mine work. Must be sober and have good references. Knowledge of Spanish desirable but not essential. Mine situated in Philippines. Climate healthy. Good pay and steady employment to right man. Address quickly. Box 181. Mining and Scientific Press.
